Arawakan (ä-ra-wä'kan) **Stock** (from the Arawaks below), the most widely diffused linguistic stock of South America, and originally forming a curious and significant link between the South and North American regional if not philological stocks. Their habitat reached from Bolivia and southern Brazil not only to the northern coast of Venezuela, but — while barred to the westward by the Colombian Chibchas or Muyscas of the Magdalena basin — occupied the entire West Indies and had an outlier of several villages in Florida. Just before Columbus' discovery, however, they had been expelled from the southern Antilles and part of the adjoining South American coast by the fierce Caribs (q.v.) from the lower Orinoco, who had seized their women for wives, most of the latter still speaking Arawal when the Spaniards found them. The larger Antilles were still Arawak, and the names given in the early West India voyages are intelligible in this set of languages yet. The Arawakans have neither the energy and cohesiveness of the Araucans, the splendid physique and fiery vigor of the Caribs, nor the political development of the Quichuas in the past; they are below the medium stature, and of no great stamina. Yet they had, perhaps owing to this very lack of savage vigor, an intellectual and artistic development and a stage of culture above the surrounding tribes: they made fictile vases decorated with grotesques of men and animals, were skilful artisans in stone, gold, and wood, and excellent weavers; and the island Arawakans cultivated not only corn and manioc for food, but cotton and tobacco, whose use the Europeans took from them. There are probably a hundred or more different tribes of this stock scattered through Brazil, Bolivia, the Guianas, Venezuela, and Colombia. Among the chief, besides those mentioned below under Arawaks, are the Manaos near that city, at the junction of the Amazon and Negro; the Waupes, Maipures, and Miranhas, in the extreme west of Brazil next to Colombia, on the llanos between the Negro and Amazon; the Goajiros on that peninsula west of the Gulf of Venezuela; the Piaroas on the Orinoco near its junction with the Meta; the Maneteneris in the northwest angle of Bolivia; the Baures and the Moxos or Mojos in northeast Bolivia, next Matto Grosso; and the Antas in extreme south Brazil, near Uruguay.

Arawaks, ä'ra-wäks (name most improbably defined "meal-eaters"— that is, of cassava bread — from a Tupi word: not more descriptive of them now than the Tupis or any other South American race except the Araucanians, and they hunt and fish as well as raise corn and manioc. Their own name is Lokono or Lukkunnu, "men": cf. Illinois, Innuit, Muysca, Alemanni, etc.), a tribe of South American Indians living on the coast of British and Dutch Guiana, across the Corentyne and Berbice rivers, and taken as the type of the great Arawakan stock (above). They are not pure-blooded, however, being mixed with Caribs, etc., in a conglomerate of plantation laborers. The term is also used in a broader sense to include all the tribes of this stock in British Guiana and the neighboring corner of Brazil, with the extension noted into Dutch Guiana: Tarumas and Atoradis of the upper Essequibo basin, Wapisianas of the upper Rio Branco in Brazil, etc., as well as Arawaks proper. All these are in a very primitive stage of culture, making marriages by abduction after orgies on corn spirits, counting descent through females, having the clan system, and practising the couvade (q.v.). The Atoradis are almost white, or not duskier than South Europeans, with fine figures, especially the women having much beauty and dignity of appearance. The Wapisianas are browner and less graceful, but their language is so soft, sonorous, and vocalic that it is the general medium of communication for trade and other intercourse among all the tribes in this region, even the Caribs; and the Atoradis have nearly abandoned their own for it.

Arax'es. See Aras.

Arayat, a-rī'at, a Philippine town on the island of Luzon, occupied by the American army 12 Oct. 1899. Pop. 14,000.

Arba'ces, a Median general under Sardanapalus and the founder of the Median empire in 876 B.C. The dynasty founded by Arbaces lasted till its overthrow by Cyrus, 559 B.C.

Ar'balest. See CROSS-BOW.

Arbe'la, now **Arbeel**, a small town in Asiatic Turkey which gave its name to a decisive battle fought by Alexander the Great against Darius at Gaugamela, about 20 miles distant from it, 1 Oct. 331 B.C. There are several large mosques in the modern town. Pop. about 6,000.

Ar'ber, Edward, an English scholar, emeritus professor of English literature at Mason College, Birmingham. He is best known through the excellent reprints of which he is editor. These include 'English Reprints' (1868–71); 'Tyndale's New Testament of 1525' (1871); 'A Transcript of the Registers of the Company of the Stationers at London' (1875); 'An English Garner' (1877–96); 'An English Scholar's Library' (1878–84); 'The First Three English Books on America' (1885); 'The Story of the Pilgrim Fathers, 1606-23' (1897); 'British Anthologies' (1899–1900).

Ar'bitra'tion, a term applied to an adjudication by persons, called arbitrators, appointed to decide a matter or matters in controversy by agreement of the disputants. Submissions to arbitration, however, should not be oral, because open to disputes, and in California and Louisiana the submission must be in writing. 2 Cal. 92; 5 La. 133. Also in New York, Code Civ. Pro. 2366. A submission to arbitration may be made at any time of causes not in court, and at common law, where a cause was pending, submission might be made by rule of court before the trial, or by order after it had commenced, which was afterward made a rule of court. It differs from a reference made by the order of a court of law. The proceeding generally is called a submission to arbitration; the parties appointed to decide are termed arbitrators, not referees; and their adjudication is called an award. This mode of settling disputes has been approved by legislatures at various times, and there are statutes in a number of States regulating the proceeding.

Legal Arbitration. — Infants and others not entitled to sue cannot submit controversies to arbitration. In general, where the owner of real estate is incapacitated in any way, and also in many cases of agency, the person having the legal control of the property may submit the matter in dispute to arbitration. Such, for example, as a husband for his wife; a parent or guardian for an infant (not, however, a guardian appointed for some other special purpose); a trustee for his beneficiary; in some instances, an attorney for his client; an agent duly authorized so to do by his principal; an executor or administrator may submit to arbitration, but does so at his personal risk should his estate be improperly held liable.

The matters that may be submitted to an arbitrator are all personal disputes and differences that might otherwise be made the subject of controversy in the courts of civil jurisdiction. The New York Code of Civil Procedure, § 2365, provides that a submission of a controversy to arbitration cannot be made (1) where one of the parties is an infant, or a person incompetent to manage his affairs by reason of lunacy, idiocy, or habitual drunkenness; (2) where the controversy arises respecting a claim to an estate in real property in fee or for life. The second subdivision of this section does not prevent the submission of a claim to an estate for years, or other interest for a term of years, or for one year or less in real property; or of a controversy respecting the partition of real property between joint tenants or tenants in common; or of a controversy respecting the boundaries of lands or the admeasurement of dower. Subject to the exceptions in this section, any controversy existing between two or more persons at the time of the submission may be submitted to arbitration. Thus breaches of contract generally, breaches of promise of marriage, trespass, assaults, charges of slander, differences respecting partnership transactions, or the purchase price of a piece of personal property, all may be referred to arbitration. Differences between landlord and tenant, where no claim of title is interposed, and pure questions of law, may also be referred to the decision of an arbitrator. Actions at law and suits in equity may be settled by arbitration; and this kind of reference may be made at any stage of the proceedings, sometimes even after the verdict, and probably, by analogy, after decree in equity. An agreement to refer future disputes will not be enforced by a decree of specific performance, nor will an action lie for refusing to appoint an arbitrator in accordance with such an agreement. (2 Bos. & P. 235; 6 Ves. Ch. 815; 15 Ga. 473; 50 N. Y. 250; 39 N. Y. 377; 35 Barb. N. Y. 602; 6 State Rep. 603.) It is well settled by authority that an agreement to refer all matters of difference or dispute that may arise to arbitration will not deprive a court of law or equity of jurisdiction. The best reason for the rule is an aversion of the courts, from reasons of public policy, to sanction contracts by which the protection which the law affords individual citizens is renounced. (50 N. Y. 250; 39 N. Y. 377.) A matter clearly illegal cannot be made the subject of a valid submission. But where transactions between parties have been brought to a close by general award, apparently good, the courts have refused to reopen them on a suggestion that some legal item had been admitted in account. It is not the policy of law to refer to arbitration felonies and other criminal offenses of a public nature, because the public safety requires them to be punished, and for this purpose they can be properly tried only in one of the ordinary courts of the country. Partners and corporations may make submission to arbitration. The arbitrator ought to be a person who stands perfectly indifferent between the disputants; but there are no other particular qualifications for the office, and the choice by parties of the person who they agree shall decide between them is perfectly free, unless it is stipulated in the agreement to arbitrate that an arbitrator need not be sworn at common law. In various States of the Union, however, arbitrators are required by statute to take an oath to hear faithfully and fairly, and examine the matters in controversy, and to make a just award according to the best of their understanding, unless the oath is waived by the written consent of the parties to the submission, or their attorneys. (See N. Y. Code Civ. Proc. § 2369.)

In matters of complicated accounts mercantile men are greatly preferred. In other cases it is usual to appoint lawyers, who, being accustomed to judicial investigations, are able to estimate the evidence properly, to confine the examination strictly to the points in question, and, in making the award, to avoid those informalities in respect to which it might afterward be set aside. Both time and expense are thus saved by fixing on a professional arbitrator.

Mode of Procedure.— The proceedings before an arbitrator are regulated generally according to the forms observed in courts of law. The arbitrator on the day appointed hears the case and makes his award, which need not be in writing at common law, for a verbal award is perfectly valid; but in practice it is usual for the arbitrator to make a written award. While at common law the award may be oral or in writing, this rule has been changed by statute in some States, and an award, to be legal in those States, must be in writing. It is provided by the New York Code of Civil Procedure, § 2372, that an award, to be legal, must be in writing. (See AWARD.) This award in its effect operates as a final and conclusive judgment respecting all the matter submitted, and binds the rights of the parties for all time. Arbitrators are allowed the greatest latitude in investigating matters in controversy. They are judges of both law and fact and are not bound by the rules of practice adopted by the courts. (2 Johns. Ch. N. Y. 276, 368; 3 Duer, N. Y. 69; 1 E. D. Smith, N. Y. 85, 265.) Arbitrators cannot delegate their authority; it is a personal trust. (7 Serg. & R. Pa. 228; 2 Atk. Ch. 401.) An award may be set aside on the ground of corruption and fraud in the arbitrator, and for any material irregularity or illegality appearing on the face of the proceedings, such as is beyond or not covered by the submission. The interest of the arbitrator in the subject-matter of controversy, his relationship to one of the parties, business relations between an arbitrator and a party, or the expression of an opinion upon the merits of the controversy, if unknown to the party injured, will warrant the court in holding an arbitrator incompetent to make an award. But the tendency of the courts is to favor arbitration and maintain awards unless such serious grounds as are above referred to can be substantiated. Where there are two arbitrators the submission often provides that in the case of their differing in opinion the matter referred shall be decided by a third person, called an umpire, generally appointed under a power to that effect by the arbitrators themselves. But they cannot make such appointment unless specially authorized so to do by the terms of the submission. This umpire rehears the case, and for this purpose is invested with the same powers as those possessed by the arbitrators, and is bound by the same rules. It remains to be stated in general concerning arbitration that from the nature of the case there can be no appeal, on the merits of the dispute submitted, to any public tribunal whatever. In New York the proceeding to vacate an award, and the grounds on which it can be made, are regulated by statute.

Court of Arbitration.— By chapter 278, laws of 1874, the legislature of New York established the "Court of Arbitration of the Chamber of Commerce of the State of New York," defined its jurisdiction, and regulated its proceedings. Gov. Dix nominated, and the Senate confirmed, the Hon. Enoch L. Fancher as the official arbitrator or judge of the court. Its work was chiefly confined to commercial matters and disputes of shipping merchants, though during its existence almost all subjects of controversy have been before the court and decided. There is no appeal from the decision of the official arbitrator; though, where a defeated party desires it, a rehearing of the case is always granted. No costs or fees to attorneys or counsel can be recovered; each party, whether defeated or not, must bear his own costs and expenses. The London Corporation and the London Chamber of Commerce founded jointly in 1892 a chamber of arbitration, or tribunal of commerce, for settling trade and commercial difficulties; and the great coal dispute and strike of 1893 led to a conference which secured a peaceful conclusion for the time and the foundation of a permanent "Board of Reconciliation," consisting of representatives both of owners and of the miners. Diplomatic conferences, which often obviate war, belong to a different category. The Parliament of New South Wales has passed an act constituting an arbitration tribunal for the purpose of settling industrial disputes. This tribunal consists of a judge of the supreme court, a representative appointed by the employers, and a representative nominated by the employees. The court has jurisdiction in the case of industrial disputes, and a lockout or a strike before allowing time for reference to the court or pending the proceedings of the court is illegal.

International arbitration has been discussed frequently and at length. It has been employed in matters of debate between nations more than a hundred times. As between the United States and Great Britain, the San Juan boundary question, the Alabama question, and the Bering Sea sealing controversy have been so arranged. The first general treaty of arbitration ever drawn between nations was signed 11 Jan. 1897, in Washington, by Richard Olney, secretary of state for the United States, and Sir Julian Pauncefote, ambassador of Great Britain to the United States, for Great Britain. This treaty was placed before the United States Senate, 11 Jan. 1897, accompanied by a special message from President Cleveland, but the Senate refused to ratify it. Since then similar treaties have been made and ratified between Italy and the Argentine Republic and between the Argentine Republic and Uruguay. The International Peace Convention at The Hague, in 1899, established an international court of arbitration which has been ratified by the United States and other signatory powers. See HAGUE COURT.

Arbitration, International. See ARBITRATION.

Arbo'ga, är-bō'ga, a Swedish city, once important commercially, but now only of historical interest from having been at one time a residence of the royal family of Vasa, the scene of Church assemblies and national diets, and for the antiquities in its neighborhood. Pop. (1901) 5,250.

Arboleda, är'bō-lā'tha, **Julio,** a South American poet and statesman: b. in Barbacoas, Colombia, 9 June 1817; d. 1862. He was educated in Europe, and on his return to Colombia engaged in journalism. In the various Colombian revolutions he was a liberal Conservative and more than once declined the vice-presidency of the republic. His poems are much esteemed in Spanish-American literature.

Arbor Day, an annual tree-planting day appointed by nearly every State and Territory of the Union, sometimes as a legal holiday and sometimes merely advisory, to assist in foresting or reforesting scantily wooded tracts, or shading or beautifying towns. It is generally in special connection with the public schools, to impress children with the importance of forestry and natural beauty in our civilization. The date depends on the climate of different sections, and is absolutely fixed in but few; most Northern States hold it in April or early in May; Arizona, Texas, and Alabama in February, the two latter on Washington's birthday; Florida in January, Georgia in December, and New Mexico in March; many make it optional either with the State or with localities, and West Virginia holds it twice a year, in spring and fall. It arose from the alarm felt by the most far-sighted public men over the rapid and reckless deforestation of many parts of the Union, and the prospects of its extending to all, the proof as seen abroad of what that deforestation meant, and the example of their governments in reforesting and conserving. (See FORESTRY.) Most civilized governments at different times have looked after their forests to assure a supply of timber for naval construction; New Hampshire and New York, even in the colonial period, felt it needful to check the inroads on them; the United States government at the beginning of the 19th century bought timber lands, and a quarter of a century later authorized the President to take measures for their preservation; and about the same time the Massachusetts Society for Promoting Agriculture offered prizes for forest planting. But the first widespread realization of its importance was caused in 1864 by the notable book of George P. Marsh (q.v.), the eminent American scholar and diplomat, entitled 'Man and Nature'; the chapter on "The Woods" aroused especial attention, and in 1865 Birdsey G. Northrop, then secretary of the Connecticut Board of Education, suggested that States might profitably plant trees every year at the proper time, or supervise their planting. The subject brought out several books and many articles; the late Dr. Franklin B. Hough, the first forest commissioner, publishing a work upon it as early as 1873. But the first to propose a regular Arbor Day for the purpose was J. Sterling Morton, late commissioner of agriculture, then of Nebraska, who in 1872 succeeded in inducing his almost treeless State to set apart a day for the purpose. Great enthusiasm was aroused, and over a million trees were planted that year. In 1885 it was made a legal State holiday on 22 April, Mr. Morton's birthday. The movement did not at first spread very rapidly, though some localities took it up; the first States to copy the legal enactment were Kansas and Tennessee in 1875, and the next year Minnesota. It was six years before another joined, Ohio in 1882, followed by West Virginia in 1883; then the tide began to rush in, and within five years 26 more States and Territories had adopted the observance. The only absentees now are Delaware, Utah, and Indian Territory, and even there it is observed in some places. ('Arbor Day,' bulletin of the Department of Agriculture.)

Ar'bore'tum (Latin *arbor,* a tree), a place set apart for the cultivation of different trees and shrubs for scientific or educational purposes. See BOTANIC GARDENS; FORESTRY.

Ar'boriculture. See FORESTRY.

Ar'bor Vi'tæ (Latin, "tree of life"), the designation of several trees belonging to the natural order *Coniferæ,* and allied to the cypress. The genus consists of evergreen trees and shrubs, with flattened branchlets, and small, imbricated or scale-like leaves. The common arbor vitæ (*Thuja occidentalis*) is a native of North America, and reaches a height of 50 feet in favorable locations. The cones are small; the young twigs have an agreeable balsamic smell; the wood is soft and light, but tough and durable. There are 60 North American species, the principal one after *T. occidentalis* being *T. plicata,* found on the Pacific coast from the region of San Francisco Bay north to Alaska. The Chinese arbor vitæ (*T. orientalis*) is also common in Great Britain. Its upright branches and larger cones easily distinguish it from the former. It yields a resin which was formerly thought to have medicinal virtues, like the wood and young twigs of the *T. occidentalis;* hence the name — arbor vitæ.

Arbutus, är'bū-tŭs or är-bū'tŭs, the designation of a genus of about 20 species of shrubs, mostly evergreen and small trees of the natural order *Ericaceæ,* natives mainly of Europe and North America. The species, many of which have smooth red branches, are often used for ornamental purposes, the smaller species in greenhouses as well as in the parks of warm temperate climates. *A. unedo,* the strawberry tree, a species from southern Europe, is often planted in California, its profusion of white or rosy flowers and strawberry colored fruits which ripen during the blossoming period of the following year being greatly admired. In Spain this fruit is used to make sugar and a kind of liquor. *A. menziesii,* the madroña, a native of the Pacific Coast States, attains a height of about 100 feet and is the hardiest and perhaps the handsomest species of the genus. *A. arizonicus,* another American species, which sometimes reaches a height of 50 feet, has white bark on the trunk, red branches, pale-green leaves, loose panicles of white flowers, and dark orange-red fruits.

Arbutus, Trailing, an evergreen creeping plant (*Epigæa repens*) of the natural order *Ericaceæ,* growing in shaded sandy and rocky soils, especially in pine woods, from Newfoundland to Florida and westward to Minnesota. It is known in New England as the Mayflower and in the southern United States as ground laurel, and is everywhere prized for its fragrant rose-colored or white flowers, which appear in early spring. Experiments in its cultivation have generally resulted in failure.

Arc, a geometrical term denoting a portion of the circumference of a circle, often cut off by

two lines which intersect it. The name is also applied to a portion of any other curve. The magnitude of an arc of a circle is stated in degrees, minutes, and seconds, which are equal to those of the angle which it subtends at the centre. Hence, counted by degrees, minutes, and seconds, the arc of elevation and the angle of elevation of a heavenly body are the same, and the two terms may be used in most cases indifferently. The straight line uniting the two extremities of an arc is called its chord. Equal arcs must come from circles of equal magnitude, and each must contain the same number of degrees, minutes, and seconds as the others. Similar arcs must also each have the same number of degrees, minutes, and seconds, but they belong to circles of unequal magnitude. Concentric arcs are arcs having the same centre. In mathematical geography, an arc of the earth's meridian, or a meridional arc, is an arc partly measured on the surface of the earth from north to south, partly calculated by trigonometry. By these measurements the earth was discovered to be an oblate spheroid.

Arc, Electric. See ELECTRIC LIGHT.

Arc, Joan of. See JOAN OF ARC.

Ar'ca, a term applied to a genus of conchiferous mollusks, the typical one of the family *Arcadæ*. The shell is strongly ribbed or cancellated, hinge straight, with very numerous transverse teeth. They are universally distributed, but are commonest in warm seas. They inhabit the zone from low water to 230 fathoms. The fossil species are found in the United States, Europe, and southern India.

Arcadius, the first emperor of the East: b. 377; d. 408. He was son of the Emperor Theodosius, on whose death in 395 the empire was divided, he obtaining the East, and his brother Honorius the West. He proved unable to govern for himself, and was a mere tool, first in the hands of Rufinus, then of the eunuch Eutropius, and then of his queen Eudoxia.

Arc de Triomphe du Carrousel, ärk dė tre'ônf dü ka'roo'zĕl. See ARCH, MEMORIAL AND TRIUMPHAL.

Arc de Triomphe de l'Etoile, ärk dė tre' ônf dü la'twäl. See ARCH, MEMORIAL AND TRIUMPHAL.

Arcesilaus, a Greek philosopher: b. 316 B.C.; d. 241 B.C. He studied philosophy at Athens and was largely influenced by Crates and Crantor. At the latter's death he became the head of the Academic School. Arcesilaus denied the certainty of intellectual and sensuous knowledge and recommended abstinence from all dogmatic judgments.

Arch, an architectural term denoting a structural form made up of a series of wedge-shaped stones, or bricks, so arranged over a door or window in an edifice for habitation, or between the piers of a bridge, as to support each other, and to carry in addition the weight of the superstructure. These stones and bricks, of a truncated wedge shape, used in building arches, are called voussoirs. The side of an arch between the crown and the springer, or skewback, is called its haunch or flank, and by old English writers of the 16th century, its hanse. The highest part of the arch is called its crown, or by the old English authors, the scheme or skeen, from the Italian *schiéna,* the back. The lowest voussoirs of an arch are called springers, or skewbacks, and the central one, the keystone. The under or concave side of the voussoirs is called the intrados, and the outer or convex one the extrados of the arch. A chord of the arch at its lower part is called its span, and a line drawn at right angles to this chord, and extending upward to the under side of the keystone, is called its rise. The impost of an arch is the portion of the pier or abutment whence the arch springs; the thrust of the arch is its outward pressure against the abutments. The voussoirs are also called ring-stones. The spandrel is the part above the haunches, or, in a bridge, the part between the arch-ring and the roadway. If the height of the crown of an arch above the level of its impost be greater than half the span of the arch, the arch is said to be surmounted. If, on the contrary, it be less, the arch is said to be surbased. The curved arch was known to the Assyrians and the old Egyptians. Sir J. G. Wilkinson considers that it existed in brick in the reign of Amenoph I., about 1540 B.C., and in stone in the time of Psammetichus II., 600 B.C. The evidence is derived from the ruins of actual buildings, but paintings appear to carry the arch back to about 2020 B.C. There is no mention of the genuine arch in Scripture, the term "arches," in Ezek. xl. 16, being a mistranslation. The round arch was brought into extensive use by the Romans, and prevailed everywhere until the 12th century A.D., when the arch pointed at the apex, and called in consequence the pointed arch — the one so frequently seen in Gothic architecture — appeared in Europe as its rival. The forms of both curved and pointed arches may be varied indefinitely. Of the former may be mentioned the horseshoe arch, a name which explains itself, and the foil arch, from Latin *folium,* a leaf, of which there are the trefoil, the cinquefoil, and the multifoil varieties, so named from the plant-forms after which they are modeled. Other arches are the equilateral, in which the centres of the circles whose intersection constitutes the pointed arch coincide with the angular points at the two sides of the base; the lancet, in which the centres of the circles fall beyond these points; the drop arch, where they fall within the base; and the segmental arch, the sides of which constitute segments of circles containing less than 180 degrees. Besides these there are several other varieties of arch distinguished by their respective forms. The names applied to arches may be divided into several classes, as referring to geometric or familiar forms, style or position in the building. The following are different geometrical forms: The flat arch, with voussoirs radiating from one centre. Arches with one centre are: semicircular, segmental, horseshoe. Arches with two centres are; the equilateral pointed arch, where the centres of the circles coincide with the angular points at the two sides of the base; the drop arch, where they fall within the base; the lancet, where they fall outside of it, and the pointed horseshoe. The common three-centred arch is called basket-handled arch, this being the form generally used instead of an ellipse. Four-centred, six-centred, and other similar forms are occasionally used. The names horseshoe, lancet, basket-handled, etc., are given because of their resemblance to familiar forms. Gothic, Roman, and Moorish

arches are names given because these forms were used in those architectural styles. Certain names are given with reference to the position of the arch in the building, such as discharging or relieving arch, where the arch is placed over a lintel to carry pressure to the sides.

Examples of arches are the Cloaca Maxima, built about 641 B.C., with three concentric rings of voussoirs, inside diameter, 14 feet; the Pont du Gard, built by Agrippa, 19 B.C., which has semicircular arches, built of Pozzuolani concrete with stone or brick facing. The longest masonry span in Europe is the railway bridge over the Pruth, Jaremcze, Austria, 213 feet wide with a rise of 59 feet, and built in 1892. This shows hollow spandrels, which are constructionally and artistically correct. The Cabin John Bridge, near Washington, D. C., which carries an aqueduct and highway, 220 feet, the largest masonry span in the world. The Wheeling, W. Va., Main Street Bridge, built in 1892, 159 feet long, 28 feet rise, is deceptive, as spandrels are hollow, but appear to be solid. The great arch now built for the Cathedral of St. John the Divine, New York, is of masonry resting on the top of piers 86 feet high. The span is 114 feet from outside to outside of voussoirs. In 1896 was built the first large concrete arch in the United States, 40 feet span, 7 feet rise, all of concrete. This was for a highway bridge. There is also a 60-foot arch of steel-concrete in Franklin Bridge, Forest Park, St. Louis, Mo. "Concrete reinforced" is the name given to the combination of concrete with steel or iron in building. Steel concrete, armored concrete, *béton armé, ciment armé,* are various terms for such construction, now coming into frequent use.

The Melan arch system was developed by Prof. Joseph Melan, using stiff steel ribs or beams embedded in concrete to form the arch ring, following Austrian experiments. Examples of Melan arch are found in Eden Park, Cincinnati, O., 70 feet span; railway bridge over Southern Boulevard, Detroit, Mich.; road bridges over the Passaic, Paterson, N. J.; Kansas Ave., Topeka, Kansas, this being the longest, having five arches, one of 125 feet, two of 110 feet each, two of 97 feet each; Hyde-Park-on-Hudson, for F. W. Vanderbilt, 75 feet span; a foot bridge in park, Stockbridge, Mass., 100 feet span, rise 10 feet, only 9 inches thick at crown; three-hinged arch, Steyr, Hungary, span 137 feet, rise only 9 feet, or one fifteenth of span,

In regard to the cost of arches compared with steel construction, a railway steel girder span 60 feet in length, with solid floor, costs about $1,600. The cost of maintenance and renewals capitalized amounts to about $400, giving total cost of about $2,000, while equivalent masonry arch would cost about $1,800. A concrete arch built in 12 hours, by 65 men, 39 feet span, 6½ feet rise, Switzerland, cost, complete, $600. The Monier method is concrete with wire netting imbedded near the soffit. Arches of long span and slight rise in building construction are being made with the Guastavino system of cohesive construction, which is practically a revival of ancient and mediæval building methods. See also ABUTMENT; ARCH, MEMORIAL; BRIDGE; BUTTRESS; VAULT.

FRANK D. BOURNE,
Architect, Boston, Mass.

Arch, Memorial and Triumphal, a monumental structure erected in honor of some prominent person or memorable event. In the custom of temporarily decorating the gates of cities with garlands and trophies, on the return of a victorious general, we can find the origin of the triumphal arch. These are similar in form whether commemorating a peaceful event or a military triumph. In the time of the Roman republic, temporary arches were erected in honor of triumphant generals. At that period, also, memorial arches or *fornices,* were erected in memory of some individual or to ornament a city, but it was not until the time of the Empire that the triumphal arch, the *arcus,* came into use, to perpetuate the glory of a person who had obtained the honors of a triumph. Arches were often placed at the entrance of cities, becoming in such a position merely a monumental form of city gate. The usual form of triumphal or memorial arch employed a high and imposing semicircular arch as its central motive, resting on heavy piers, which were decorated generally with Corinthian columns and other architectural details, statuary, and bas-reliefs. Above this was a heavy mass of stone-work or attic, on which was placed a suitable inscription. The arch of Titus, at Rome, is the most remarkable for its purity, the beauty of its sculpture, and the harmony of its proportions. It was probably erected by Domitian in honor of Titus to recall his conquest of Jerusalem. In panels on the inner sides of the piers are sculptured, on one side the triumphant Titus on his *quadriga* surrounded by soldiers; on the other side the triumphal procession, with the spoils of the Temple, the sacred vessels and the seven-branched candlestick. At the foot of the Capitol, at the side of the Forum, is the arch of Septimius Severus, erected in honor of this emperor and his two sons to commemorate their victories over the Parthians and the Arabians. It has small side arches reached by a few steps, and a large central arch. The most important arch in Rome is that to Constantine, which is similar to that of Septimius Severus. It was erected by the Senate and the Roman people in honor of Constantine. The arch of Trajan at Ancona was erected on a pier which serves as a base, and was a memorial of the completion of that port. It is said that another arch of Trajan at Benevento was erected to commemorate an extension of the Appian Way. In modern times the name triumphal arch is given to a structure of wood or staff decorated with flags, banners, and floral designs, as a part of some public celebration, or in honor of some person; for example, the Dewey arch, in New York. This is an outgrowth of the old Roman idea. Modern history has illustrations of many examples of this form of arch. Albert Dürer has many engravings of the triumphal entry of the Emperor Maximilian, and of the arches erected in his honor. There are also illustrations of arches for Charles V. at Boulogne; to Henry III., at Lido, on his trip to Venice. Rubens made the designs for the triumphal arch for Ferdinand of Austria at Antwerp, and a large arch was erected to Louis XIV. at the Barrière du Trône. There are also triumphal arches in Paris: the Arc du Carrousel near the Louvre, built by Napoleon I., now destroyed; Porte St. Denis, built by Louis XIV.; the large Arc de l'Étoile, dedicated by Napo-

leon to his soldiers and sailors; and Porte St. Martin (1674); in Berlin the Brandenburgerthor at the entrance of the Thiergarten. In the United States there are arches of this character in Brooklyn and Hartford, Conn., and the Washington arch, in New York.

Among celebrated arches of this character, mediæval and modern, may be named the following gateways: At Naples, the Arch of Alfonso of Aragon (1470), and the Porta Capuana; at Burgos, the Santa Maria; at Montpellier, a 17th century memorial of the revocation of the Edict of Nantes; at Milan, Della Pace; at Munich, Sieges Thor (Victory Gate) (1850); and at London, the Marble Arch. See ARCH; GATEWAY.

Archæan (är-kē'ăn) **Period,** a term applied to the most ancient division of the geological time-scale. The rocks referred to this period underlie the oldest sedimentary and fossiliferous strata and hence are often called the fundamental complex. They are entirely of crystalline character, consisting of granite and basic eruptives, gneisses, and schists, all of which bear evidence of having undergone great disturbance and metamorphism, so that it is impossible to work out any order of strategraphic succession that will apply to different regions. Their great uniformity of composition over wide areas, their marked characteristics which differentiate them from all other groups of rocks, and their basal position in the geological scale have led many geologists to believe that the Archæan rocks represent a portion of the original crust of the earth as it solidified from molten magma. While this view has not found universal acceptance, it is quite certain that if the first solidification of the earth is still preserved anywhere, it is present in this formation. The Archæan rocks are known to occur in all of the continents, although in some regions they have been brought to the surface only after long periods of erosion during which immense thicknesses of overlying strata were removed. In North America they cover much of the region between the Arctic Ocean and the Great Lakes, and are also found in the Adirondacks, along the Appalachians, and in the Rocky Mountains. They occur in many parts of Europe, especially in Scandinavia, France, Germany, and Austria, in eastern Asia, and in central Africa. See GEOLOGY.

Archæological (är-ke-ō-lŏj'ĭ-kăl) **Institute of America,** a society formed in 1879 for the purpose of promoting and directing archæological investigation and research. Under its direction several important excavations were conducted on the site of the ancient city of Assos. It publishes a bi-monthly 'Journal,' which is its official organ. It has a membership of 1,050. President, Prof. John Williams White of Harvard.

Archæology, är'ke-ŏl'ō-jĭ ("antiquity-study"), the history of antique human progress as inferred from relics of man's industry or presence, apart from written records. It is thus identical with history where there are no such records, and supplementary material for it when they exist. It is distinguished from anthropology as concerned chiefly with industrial and artistic rather than social and political progress. But its limit neither of date nor of subject can be sharply fixed. The antiquities of a country are relative to its present and its records; 400 years in Mexico brings us to pure archæology, 2,000 in Greece and Rome is almost this side of it, all west-Asian history belongs to it. Even written records, if inscriptions on stone or brick, or papyri, are archæological when pertaining to an extinct civilization; if classical, they are history, epigraphy, or palæography. Nor can we wholly dissociate the biological study of the bones found in a prehistoric camp, river drift, or cave (palæontology), from that of the flints, worked bones, drawings, etc., found with them, as evidences of mechanical and intellectual progress (archæology), and the social organism implied by the camps, food, ruddle, etc. (anthropology). The genesis of the science restricted the name at first to remains of classical art and architecture, still often regarded as its most important section, through its illumination of classic literature: but general archæology does not merely supplement a developed history, it reveals the very existence of empires, nations, races, cultures, stages of human progress, otherwise unsuspected, and carries our knowledge far into the geological past.

The classical branch, whose material was relatively accessible and its bearing obvious, naturally originated first in the 18th century; general archæology is the creation wholly of the 19th century and has two independent origins. On one side it springs from the decipherment of the Egyptian hieroglyphs, unveiling a remote history implying a still more remote one, and making scholars realize for the first time how futile were the distorted scraps of classical tradition. This was followed by excavations in Mesopotamia which uncovered the remains of the Assyrian culture, and by the decipherment of the cuneiform characters. Here it was first realized that archæology is the one branch of history (for numismatics is a department of archæology) that absolutely settles historical questions. A written statement may be a falsehood or mistake, but an inscription is conclusive as to its date and writer. On the other side, archæology springs from the examination of relics of antique man in burial mounds, kitchen middens, lake dwellings, caverns, and river drifts, showing his co-existence with animals long extinct and in geologic ages long gone by. These two streams have gradually resulted in a vast storehouse of verified knowledge, not only

unsuspected, but revolutionary of truths previously supposed axiomatic. Briefly, archæology has shown that civilization is not a sudden mushroom growth of a few dozen centuries, from a single centre and a highly developed group, but a gradual evolution through enormous ages, in all parts of the world, from savagery. In place of the convenient division into "civilized, half-civilized, and barbarous," we have many stages of culture, based on the knowledge of natural forces, the utilizing of natural products by art, and the co-ordination of social groups, in combination almost as endless as the notes of an organ, the same tribe being almost civilized on one side and wholly savage on another. The classification of these grades is somewhat different in archæology and anthropology. The latter, in Lewis H. Morgan's system (which needs much qualification) marks seven stages: the first prior to the use of fire; the second marked by the discovery of fire and of catching fish; the third by the bow and arrow; the fourth by pottery; the fifth by the domestication of animals, or the use of irrigation, polished stone or bronze tools, and the occurrence of adobe or stone architecture; the sixth by the use of iron; the seventh, or true civilization, by phonetic alphabets and written records. Archæology, however, finds it convenient to classify man wholly according to the material and construction of his implements, these having in fact accompanied and determined with great accuracy a corresponding set of changes in industrial arts and even social development. Accordingly it divides human progress into the Eolithic ("Stone-Dawn"), the Palæolithic or Old Stone, the Neolithic or New Stone, the Bronze, and the Iron Ages; a portion of these being still further subdivided.

For vast epochs after the appearance of man upon the earth, no record of his presence exists or can exist except a palæolontological one — his bones. He doubtless wrenched off tree-branches and threw or hammered with stones, like the higher simians, but we cannot prove a broken branch or scratches on a stone to be artificial, or due to man rather than to orang. When, however, a stone is rubbed, or evidently bruised from repeated use, still more when a number of these are found near together, we know that something more than casual use by an animal has produced the result; but it may mark only the utterly unrisen savage, who lives on nuts and fruits and sleeps under any casual tree or bank, and has not thought of improving on nature. The first identifiable stage of real culture is:

The Eolithic Age.— This probably began (probably elsewhere also) in Kent, England, where loose flints lay about or might be easily dug from the chalk. These were very roughly hammered into an edge that would bruise off a stick or into a grip for the hand: so roughly, indeed, that their having received deliberate art at all was long bitterly contested. They are found in river deposits on the top of hills 600 feet above the present stream-beds, which must therefore have been excavated since. Even in this remote antiquity man was no new organism on the earth, and this stage of culture, from the excessive slowness of progress in the early stages, must have lasted for a long period.

The Palæolithic Age succeeded; the forme. till recently was reckoned a part of it. It is now further divided into two chief periods, from the anthropological differences implied, those of the river gravels and of the cave-dwellers; and the latter again into three others, with well-marked stages of culture. More specifically:

1. River gravels up to 200 feet above present beds ("Achuleen"). The remains are massive flints scarcely less rude than the former, but unmistakably worked. They still antedate any permanent dwelling or shelter.

2. Cave-dwellers. Man has now a permanent though not artificial dwelling, and the germ of family life is born. (1) "Mousterien": Flint flakes split off (the first true artificial tool), and massive flints hammered into definite shapes, with others rude like the former. (2) "Solutrien": Flints carefully worked and finely shaped. (3) "Magdalenien": Well-shaped flint tools, plentiful bone-working with them, and drawings on implements and the walls of caves.

All these remains have been found along with fossils of the mammoth, cave-bear, cave-lion, sabre-toothed tiger, and other extinct forms, in ancient river deposits, deep under stalagmitic accumulations in caves, beneath American lava-beds, etc. The age assigned to these deposits by geologists is from 100,000 to 300,000 years. Another clue of the same significance is the circumstance that in Egypt flints are found together, of which the latest, Neolithic, were dug and worked fully 7,000 years ago, and are tinged only a faint brown, while others, Palæolithic, have turned nearly black. The most conservative estimate is 100,000 B.C. for the beginning of the Eolithic period; the Palæolithic has not ended yet, but in the advanced regions it began to be displaced by the Neolithic perhaps 10,000 B.C. Roughly speaking, the Old Stone periods cover a space ten times as long as all those since put together, the latter succeeding each other with relative swiftness, as progress accelerates by its own development. In some respects the 19th century has shown more advance than all the previous half-million years of man's existence. The rate of progress has depended greatly also on the natural advantages offered: the flint mines of the English chalk hills with the early savage perhaps corresponded to the coal- and iron-mines of the present, producing rapid advance in skill and also competition of tribes, the stronger expelling the weaker from the coveted districts. On the other hand, the lack of domesticable animals in America had much to do with its slight progress under barbarism.

The Neolithic Age is the evident beginning of modern life, made possible by improved working tools. The remains of this period are not buried under geologic deposits, but lie on or near the surface. They are no longer merely hammered or chipped, but rubbed or ground to shape, giving a sharper edge and a smoother surface. There is a gradual advance in the best specimens to weapons and tools almost equal to metal, such as lance-heads, arrow-heads, knives, daggers, awls, chisels, and axes of razor-like sharpness, and needle points, serviceable for and accompanied by highly-developed arts and manufactures, agriculture, and navigation, of remarkable magnitude and variety. As timber could now be easily cut, men built large wooden dwellings and rowing galleys. Early in the

period we find immense earthworks both for defense and for burial; later, in the cities, brick architecture and fine engineering. The lake dwellings of central Europe and England belong to this period, and, being built on piles over the water, combined security against wild beast and animals with easy fishing, a fashion that spread widely and no doubt rapidly: indeed, some of them with their Neolithic inhabitants lasted into historic times. From these discoveries it is evident that man not only hunted and fished, but raised grain, vines, fruit, and flax, breeding domestic animals to draw the plow, another immense gain to agriculture; spun and wove; made pottery; and not only ornamented that but his tools as well, shaping them for beauty as well as use, thus showing development of æsthetic taste. Still more important was the social development. The large camps indicate a settled tribal society, the careful selection of material from considerable depths indicates combined labor in mining.

Between this and the Bronze Age there existed in some countries what is called by some archæologists a Copper Age, where native copper was hardened with oxid or arsenic; but as it did not drive out flint tools, but only supplemented them, it is hardly entitled to be called an epoch, and is not accompanied by any identifiable advance in general progress consequent upon it, like the others.

The Bronze Age, however, was an enormous step forward. It was earlier in Assyria than Egypt, probably from the Armenian copper: the former introduced it by 5000 B.C.; the latter not fully till about 3000, and did not use it freely till 1600, only 500 years or so before iron displaced it. And in all countries stone implements were still used in sacrifices to the gods, who did not like new inventions. The hardness of the alloy of copper and tin seems to have been realized before its toughness and the many advantages given by ability to cast it; hence at first the stone tools and implements were simply copied in massive bronze, and were needlessly heavy and limited in pattern. But as its properties became evident the tools were much lightened, and made thin yet stiff with embossed patterns, and various kinds invented which could not have been made in stone, as the sickle, gouge, etc. The axe, or celt, was first made as a plain bronze wedge fastened by a thong, as with stone; then cast with a socket for the helve, an extraordinary gain in efficiency. There were light cups and kettles, knives and chisels, spear- and arrow-heads, swords and daggers, and bronze-bound shields, and a mass of personal fastenings and adornments. Some of these were impossible in stone, as buttons, buckles, and pins, necklets, bracelets, rings, and earrings. A priceless collection of these objects was found at Bologna, Italy, in the shape of the abandoned stock of an ancient bronze founder. The industrial advantage of this newly found hardness, toughness, and variety developed industries and trade immensely; it also made possible for the first time true stone architecture, and engineering of hewn and dressed stone. No small branch of business in stoneless Egypt was the quarrying and transportation of stone for the public works from the southern rockier regions.

The Iron Age is the present (though the 19th century developed what is really a distinct era, the Steel Age, making possible many advances beyond the mere iron), and the most of its course belongs to history. It originated from about 1200 to 1000 B.C.,— that strange period, in seeming the blackest in the calendar of the ancient world, when the old civilization of Mesopotamia had collapsed under the Semitic invaders, Egypt had sunk into decay, and barbarism seemed to have reasserted its reign over both the Eastern and Western world; yet in which lies the birth of perhaps the three greatest factors of human progress in historic times,— the use of iron, the alphabet, and the Hebrew nation. The first is thought to have sprung from Armenia; regarding the second, the Phœnician origin is still valid; the third is a mysterious gift of Arabia.

Babylonia and Assyria.— The civilization of the Mesopotamian plain is not only the oldest in the world so far as known, but the first (unless with the possible exception of Egypt) where men settled in great city communities under an orderly government with a developed religion, practising agriculture by irrigation, erecting adobe buildings, and using a syllabified writing. All modern Western civilization is its direct descendant through Greek and Roman periods, so that in studying it we are studying our own ultimate intellectual and even religious pedigree. Its astronomers gave us the division of the year into months, weeks, and days, the signs of the zodiac, the constellations, the division of the circle into degrees; its art was the foundation on which Greek and Etruscan art was built; its religious names, forms, and traditions are a deep element in the Hebrew, as in its cosmogony and mythology and such forms as the Psalms, and hence enter into Christian thought. Nor are we the only beneficiaries. For some 6,000 years the cuneiform was the business and literary script of the whole civilized world, the one method of writing from the western Mediterranean to India, and probably the origin even of the Chinese, as Mesopotamian civilization was the parent of Chinese civilization.

The physical difficulties and dangers of exploration in this district (once a garden and turned into a desert by Turkish misgovernment, a region without supplies or administrative order, and infested by hordes of dangerous Bedouin), as well as the difficulty of obtaining justice or possession of one's goods from the Turkish authorities after finding them, have kept it far behind that of Egypt in thoroughness; but the results have been not less splendid in additions to our knowledge of the past. The earliest studies — those of J. B. Rich, Indian consul-general at Bagdad, in 1818–20, who collected sculptures and outlined Assyrian art: the excavations by the French consul Botta at Khorsabad in 1843, of Nimrud and Nineveh by Layard in 1845–51, and Hormuzd Rassam in 1854 — were of relatively modern Assyrian sites. The first entrance on the ancient Babylonian civilization was made at Erech (1849–52) by Loftus; a further one by Sarzac in the important Tello excavations of 1876–81; but by far the most important was by the Americans, Peters and Haynes, with Hilprecht, at Nippur from 1889 down. This was probably the first city foundation in the world, dating from about 7000 B.C., then a seaport and now 120 miles inland; and the great temple library has poured

floods of light on the political and social condition of this mother-land of modern culture. Next to this, our greatest source of information — for Babylonian history almost the whole — has been the library of Nabonidus, the last king, at Babylon. The whole fabric of Assyrian chronology rests on his statement that Naram-Sin, the son of Sargon, lived 3,200 years before his time: a suspicious number, the dubiousness of which leaves half that chronology a thousand years or so doubtful. But the subject was practically sealed till the decipherment of the inscriptions gave the key; and this was immensely complicated by the fact that the cuneiform character, like the modern alphabet, did not imply any given language, but was used for all the tongues of the then civilization. The first step was taken in 1800 by Grotefend, who identified Persian names and then applied the characters to other names, till he made out several Persian inscriptions, and Bournouf (1836) and Lassen (1836–44) worked out the rest of the Persian alphabet. But this was only a small part of the enormous Assyrian syllabary of 600 signs. The task was finally accomplished by Sir Henry Rawlinson by means of the great trilingual Behistun (q.v.) inscription, in Assyrian, Median or Vannic, and Persian: his knowledge of old Persian gained from Zend and Sanskrit enabled him to identify the Persian words in Assyrian character, and thus resolve the vast Assyrian syllabary. This has given the clue in turn to the other languages written in the cuneiform: the old Sumerian, Median, etc.

The general results are as follows: The earliest inscriptions show us a mixed people speaking two languages: one certainly Semitic, the other either an archaic Semitic or Aryan (the Ural-Altaic affinity is now discredited). The non-Semitic element, known as Sumerian ("river-men"?) is believed to be Aryan, related to the Caucasian tribes, and to be the original settlers of the valley. Into this valley came, somewhere between 10000 and 8000 B.C., a Semitic invasion (Accadians, = "highlanders"?) from the upper Euphrates-Tigris valleys, and by 5000 B.C. had developed, through the mixture of two powerful stocks, the wonderful civilization we know. The beginnings were in the Neolithic Age, but by 7000 B.C. the people were already organized into nations, and built fortified towns, the centre and heart of each being the temple of the local god, raised on immense piles of brick-work. They had finely colored and ornamented pottery, made with the potter's wheel. The principle of the arch was known as early as 5000 B.C.; the architecture was careful and related to the nature of material; drainage systems were constructed to prevent soaking into the adobe. Several important centres existed by about 7000 B.C., including Nippur, Ur, Eridu, and probably Erech. When we first find inscriptions, perhaps about 4000 B.C., there had already been evolved from the old picture-writing a system of conventionalized line-symbols, some pure pictographs, some ideographs, some syllables; and while at first the writing was entirely votive or commemorative, and stone used as the material with straight lines, it was soon applied to business and record, the ever-present clay utilized, and the lines assumed the familiar wedge or cuneiform shape. Sculpture and the engraving of gems and gold were already at a high level shortly after 4000.

The history will be found under Assyria and Babylonia. The great landmarks are the reign of Sargon, the Charlemagne of the ancient world, who founded a huge west-Asiatic "empire" from north Arabia to Armenia and west to the Mediterranean; the second great Semitic invasion from Arabia about 2500 B.C., overrunning south Babylonia, and the Elamite invasion from the Karun valley in Persia about 2300 B.C., subjugating the remainder; the expulsion of the Elamites about 2250 by Hammurabi ("Amraphel"), and the founding of Babylon, which became for 17 centuries the Rome of the Asiatic world, the political and religious centre at once; the first emergence of Assyria, on the Accadian highlands, about 1800; the Kassite invasion from the Persian highlands 1782 B.C., founding a dynasty which ruled Babylonia till 1207; their expulsion; the great double invasion of Semites from the south and Aryans from the north, which broke up the Hittite empire and overwhelmed Babylonia and Assyria in a common wreck; the collapse of the Old World civilization; the re-emergence of Assyria and its domination over Babylonia, from about 900; its eclipse by the growth of Armenia in the 8th century; its new and enormous power under Tiglath-Pileser II., who annexes Babylonia; the destruction of Babylon by Sennacherib, 689 B.C., and its rebuilding by his son Esarhaddon; the rebirth of Babylonia under Nabopolassar the Chaldæan, who extinguished Assyria, 610 or 609 B.C., and, after a short, brilliant career, the end of the Babylonian-Assyrian power forever through its conquest by Cyrus. The relation of the Assyrian power to the Babylonian was much like that of Rome to Greece; though on a lower scale, for the Assyrians, though great warriors, had none of the organizing and assimilating power of Rome. Assyria copied laboriously, and on the whole clumsily, the literature and art of its intellectual masters, and produced no literature proper of its own. But its libraries, copied from the Babylonian tablets with minute textual and critical accuracy, give it an imperishable claim to our gratitude.

Egypt.— The archæological history of prehistoric civilizations was studied in Egypt earlier, and has been studied there more fully, than elsewhere, from the accessibility of relics and safety of work, the involution of Egyptian politics and history with records in a classic language through the existence of an Egyptian state under classic rulers, and the survival of a descendant of the Egyptian language to our own day. It was the latter which furnished the key to the decipherment of the hieroglyphic records. The Rosetta Stone (q.v.), discovered by the French in 1799, bearing a proclamation in hieroglyphic, demotic, and Greek, invited a textual comparison. An Englishman, Young, devised a correct principle, but had neither knowledge nor interest to apply it in full; Sir William Gell utilized his knowledge of Coptic, and identified three fourths of the signs; Champollion, the Frenchman, was a thorough Coptic student, and in 1821–32 worked out the entire system for use. This first made it possible to rescue Egyptian history in preclassic times from the fog of distorted Greek legends, scraps of priestly record, and misapplied Biblical compari-

sons, while the excavations at Thebes in 1820–30 opened up the Ramesside and neighboring periods 1500–1000 B.C. Later, Lepsius and Mariette were foremost in revealing the period of the Pyramid-Builders, carrying us back to far past 3000 B.C.; and still later Dr. Flinders Petrie has not only turned the First Dynasty and others still farther back, from myth into solid history, but has recreated the prehistoric world prior to the organization of the monarchy, about 4800 B.C., with a surety as great as that of written record. In the historic periods, the total lack of any chronological sense in the Egyptians, who in this respect were very different from the Assyrians, and the catastrophe of the Hyksos invasion, make its history in large portions less clear than the Babylonian; but we know its general outline at worst, and the synchronism and variations of arts and industries often supply the lack of dated chronology.

The oldest inhabitants of upper Egypt known were of the same race as the Algerian Kabyles of to-day,— a white-skinned, blond, blue-eyed, narrow-headed race, with a negro strain, allied to the south European races. They had acquired by 5000 B.C. the highest grade of Neolithic civilization ever reached in the world, so far as evidenced by tools and implements,— the finish of the flint-knives and lances being incomparable,— and were using copper ones also. They built brick towns, and carried on an active Mediterranean commerce in large rowed galleys; they made leather and woven linen clothes, beautiful and varied pottery without the wheel, perfect vases of the hardest stone without the lathe, applied colored glazes even to great rock carvings, manufactured ornaments of precious stones, metals, and ivory, ivory spoons and combs, games, etc. Their art, however, was very crude, and they had no system of writing whatever, though using marks. About 5000 B.C. a much more developed race invaded Egypt,— probably from Arabia, whence the Hyksos and the Hebrews and the other Semites came: a race which used metals more freely, had a system of writing, a better government organization, and higher artistic taste. Here, as in Assyria, the blending of two able but diverse strains made the great Egyptian type and civilization of the Old Kingdom, which we know from their monuments and achievements. They were a grand people in every way: active warriors and administrators, firm in policy, fine mechanicians, adepts in organizing combined labor; strong artists, with lofty conceptions; withal a sensitive, kindly, sympathetic folk, with the least strain of ferocious savagery of any great people in history. This long era has left us the Pyramids and magnificent monumental tombs, masses of grand and accurate architecture, and noble sculpture. This great age could not last forever, and for some centuries after about 2500 B.C. it was in decline, to revive only less brilliantly in the Twelfth Dynasty about 2000 B.C., considered by Egyptian writers their Golden Age of art and literature. The tremendous catastrophe of the Hyksos invasion, already mentioned, took place probably about 1780 B.C., and the «Shepherd Kings» remained till about 1600. Their final expulsion opened a new and brilliant era, of expansion into and domination over west Asia, of the closest relations with the Mediterranean countries, of a general spread of luxury through the people Egypt for the first time threw off its exclusion and became part of the current of the world's progress. In this period (about 1600–1200) we find, near the beginning, the great Thothmes III., whose exploits were exaggerated into the Sesostris of Greek tradition; near the end the rather braggart King Rameses II., commonly identified with Joseph's Pharaoh, and his son Merneptah, often accredited as the Pharaoh of the Exodus. But the empire had the doom of all states which live on the tribute of foreign districts: the outside revenue stopped, the habits of luxury remained, and the nation declined. In the thousand years to follow before it was absorbed in Rome, it had much prosperity and some periods of brief glory, but the vital spirit had gone.

Syria.— While the work of the Palestine Exploration Fund, from 1866 onward, has thoroughly mapped out the surface of the country, relatively little has been done in excavation here or in Turkey; for political reasons (as before noted) mainly, as the interest in Biblical sites and classical remains is the keenest of all. The chief part thus far has been at Jerusalem and the Philistine cities, and in the north at Zinjirli; but few inscriptions have been found even where the excavation has been done, and no very ancient ones. The most important historically is that of Mesha, king of Moab (? 896 B.C.). It would seem that by the time the Jewish nation was advanced enough to make inscriptions, its intellectual activity was drawn off in other directions, and the hope of finding masses of archæological confirmation of or supplement to Biblical records has been disappointed. The chief historical result of Syrian research has been to restore the Hittite empire (q.v.) to history: formerly regarded as a Canaanitish tribe, it is now known to have been a powerful people from Cappadocia, which formed for a couple of centuries a strong state ruling north Syria and much of Asia Minor, with its centre at Carchemish, till broken up by the great southward Aryan movement of which the Dorian invasion was a part. Its writing is almost undeciphered. Curiously enough, the most important documents for ancient Syrian history have been found not in Syria, but in Egypt,— the Tel-el-Amarna tablets, containing a 15th century correspondence with Egypt in cuneiform.

Classical Archæology.— Till the very recent excavations at Troy, Mycenæ, etc., resulting from enthusiasm for the Homeric poems, archæological research in the classic lands was mostly confined to illustrating historical periods, and to a study of Greek and Roman art and architecture; even now the light on prehistoric times is not from written records and inscriptions as in the East, but inferential from material objects. It has, however, in confirmation of Egyptian and other records, and by comparison of objects with those of known date in that country and Babylonia, given unmistakable proof of a hitherto unsuspected stratum of old Greek history. From foreign pottery found in Egypt, 5000–3000 B.C., Greece and Italy probably had a Neolithic pottery-making population at those times. But the first positive beginning of civilized settlement is in the lowest Troy, dating certainly before 2000 B.C., and perhaps 3000: almost no metal is found there. Still before 2000 is another Troy,

with fine vases and golden ornaments. This was contemporary with the supremacy of Crete, then the mistress of the seas, as the Etruscans and Phœnicians were later; and there was a direct connection between Crete and Troy. The legends of the great law-making Cretan kings and their suzerainty over Greece and exactions of tribute from it are doubtless based on fact; even the Labyrinth has been uncovered, and a nucleus of fact in much of the old Greek legendary lore made probable. Three times after this was Troy abandoned and rebuilt before the contemporary of the Mycenæan kingdom of about 1500 B.C. is reached. At this time the coasts of Greece and the Ægean islands were the seat of a high culture radiating in all directions, and even influencing the East, so that this has been styled the "Ægean Period" of civilization. There was a powerful and wealthy kingdom with its centre at Mycenæ, where we find magnificent domed tombs, fine jewelry and metal work, exquisite pottery and ornaments, etc.; as also at other great towns marked by hill fortresses, Athens, Tiryns, and other places. This rich and prosperous land traded with all the Mediterranean countries, but chiefly with Egypt, in whose ruins are found hosts of Greek objects of this period. By 1100 B.C. this civilization had begun to droop, and about 1000 the invasion of the barbarous Dorians from the north temporarily overwhelmed it on the mainland. But it was only for a time: even where the Dorians had conquered, the union of old and new flowered into richer bloom, and Athens, the chief city which they had not conquered, became the head and heart of a far more splendid revival of every art and literature, the foremost in the world to the present time. By the 7th century the immortals had begun to spring up: Archilochus and Sappho were islanders, and the great time of Athens had not yet come, but the thronging masters show that society had become fairly settled once more.

The development of civilization was very much later in Italy than in Greece, and more slowly affected by outside civilizations except on the southern coast. The Neolithic Age, with black pottery and lake dwellings, lasted down to nearly or quite 1000 B.C., the full development of the Bronze Age not taking place till about 800. The Etruscan invasion, which tradition brings from Asia Minor, cannot be dated, but was probably later than 1000 B.C. The art and religion of the Etruscans were entirely foreign, indicating rather a Northern than an Eastern origin; but they were not an original people, and borrowed elements of civilization and art from every nation they came in contact with.— Italians, Greeks, Egyptians, and Assyrians. In this assimilativeness they remind one of the Northmen, and the tradition of their origin may be wholly wrong. The one great specialty of the Etruscans was engineering. Their history and affiliations remain a mystery chiefly because their language is such. Known since historic times, and in the last century thousands of inscriptions in it copied, and even many words translated for us, the language remains an absolute secret to the laborious and penetrating scholarship directed on it.

Archæology, American. America's place in the world's history has been an abundant source of discussion among geologists and archæologists, and there exists still a wide range of opinion, particularly concerning the antiquity of man on this continent. There is uniformity of opinion as to the occurrence in definite superficial strata of traces of man's handiwork, but the geological history of these strata has been variously considered. It is now generally concluded, however, that they are a product of the concluding activities of the Glacial Epoch, material laid down by floods caused by the melting of the glaciers that filled the valleys, and not improbably accompanied by rainfall far in excess of any in post-glacial times.

As yet the evidences of man's antiquity may be summed up in the discoveries made in the valley of the Delaware River (1872–1902) on the Atlantic slope, and the shell-heap discoveries (Dall) on the Pacific slope. In the interior of the continent there have been many reported discoveries of evidences of equal antiquity, but so generally were they open to possible errors of observation, due to lack of skill required in such investigations, that their acceptance has not been general. This is true even of the much-discussed Calaveras skull and Nampa image. This, however, is not true of the human cranium known as the "Lansing skull," from Kansas, and the age of the deposit in which it was found only is in dispute. Much more satisfactory is the result before mentioned obtained by Dall in his investigation of the Pacific coast shell-heaps. Here we have evidence of a gradual change of habit, of a succession of occupations of the region that enables us to deal with "time relative" if not "time absolute," and to feel assured that man's first appearance on the western coast of North America was in the extremely long distant past as measured by years. As shown that traces of man occur in deposits on the Atlantic coast, notably in the valley of the Delaware River, the dual question arises just when and whence came man to the American continent? It is inherently improbable that he did so while glacial conditions obtained in the northern half of the country, for in that case he would have confined himself to those unglaciated regions in the south, where the struggle for existence was reduced to its minimum. It is far more probable that his arrival on the continent was pre-glacial and that when driven southward by the steady encroachment of the ice-sheet he lingered at its southward limit of extension and lived in a manner not essentially dissimilar to that of the present boreal races, but more favorable in that the fauna was richer than that of the circumpolar regions of to-day. This is not to say that the glacial man of the Delaware valley and the Eskimo of to-day were racially the same, but merely that similar physical conditions would produce essentially the same modes of living.

It can scarcely be questioned that man originally was a tropical animal, and the existence of boreal races indicates that primitive man was slowly differentiated and, spreading over the earth, so far changed in habit as the environment required. Pre-glacial man — at least in North America — is yet to be demonstrated by unquestionable discoveries of his remains, but theoretically nothing can be more reasonable than the claim of his one-time existence.

From what other continent man came to America is still an unsettled question. The

necessity for an ultra-American origin is insisted upon, perhaps illogically, but, accepting the necessity, a migration route is fancied from the direction of Japan or directly across Bering's Strait from Siberia, and that North America was peopled by an incursion of wandering humanity into the northwest portion of the continent, and thence followed down the Pacific coast and finally spread eastwardly until the Atlantic checked the movement. That the Japanese archipelago was the «home» of the first American is possible, so far as our present knowledge warrants our forming any opinion on this point; but, accepting this or another Asiatic origin of this country's «first» people, it is clearly evident, from the traces of them that have been recovered, that the trans-Pacific migration occurred in what we know as pre-glacial time, and so, so far in the past that race-differentiation had not progressed to an extent at all comparable to what has since occurred. The pioneer invaders of the American continent were doubtless much the same as folk wherever found at that time; in other words, still very near to that primitive condition in which man remained so long after losing all visible traces of its pithecoid ancestry. If such was his condition, man might well have wandered over a wide territory, tracing each river's valley, up or down, as the case might be, and, depending upon his physical strength and the simplest of weapons, it is little wonder that no recognizable traces of him should be found. His inventive ingenuity was subsequently developed, and it is in tracing this from its humblest manifestations to the degree of skill in tool-making ultimately acquired, that the archæologist is able to demonstrate that man in the lowest state of savagery originally peopled this continent, and that there has been here a growth or development of human faculties which may be considered strictly indigenous. This advance toward what we call «civilization» reached its highest point in Mexico, in Central America, and in Peru. That it was influenced in Mexico and Central America, if not elsewhere, by an occasional influx of Asiatic people who had outreached their distant cousins, is persistently claimed; and certainly, if at a far more remote period an Asiatic savage had reached this country, it is not improbable that such an occurrence should happen in later time, when savagery had given way to a higher cult and travel by land and water was a less formidable undertaking. Such influence may have been impressed at times upon the growing American civilization, but never to such a degree as radically to change its character. The American race was too firmly fixed to be wholly altered, and whatsoever reached it from the East in recent times — geologically speaking — made but an inconsiderable impression.

Dating, then, the appearance of man on this continent at the close of the Glacial Epoch (q.v.), and inferring only that his career really commenced in pre-glacial time, we find him a rude chipper of flint-like stone, fashioning implements so nearly identical with the palæolithic forms of other continents that it is logical to assume that his general mode of living and mental attainments were the same as those of the river-drift man of Europe. This, when the activities of glacial conditions were at their height; but as these waned, slowly a change took place. Faunal changes certainly occurred, and these may have been the direct cause of the alterations in implement forms; for it is at this time that the more specialized and smaller objects, intended for smaller game, appear; among them the arrow-head. These are found in the alternated layers of sand and clay that overlie the coarse gravels due to the torrential floods that marked the beginning of the close of the great Ice Age. These stone implements are almost wholly made of argillite — laminated slates that have been fused by volcanic heat — and are the traces of an intermediate period between palæolithic man proper and the historic Indian.

This intermediate period was one of immensely long duration; one during which the surface was but sparsely clad with vegetation, and tree-growth limited to coniferous forests that had grown for ages beyond the reach of the encroaching glaciers. It was during this time that the bow came into use, and there was a faint foreshadowing of the manifold activities of later date, but as yet no pottery. It was now that the surface soil began accumulating, here and there in favorable spots, and finally until the old half-barren sands were covered. With this change vegetation increased until the flora was what we now find it. Deciduous trees grew where the soil was moist, and at last the country was concealed by forests. It was not until then that the Indian occupation of the country really commenced. As we know him, he is strictly a creature of the soil and not related to any of the older, underlying sands. He is a man of history, and of that misty borderland of history and geology known as prehistoric time. That there was an interim, when the «argillite» man was absent and the flint-chipping, pottery-making Indian finally appeared, has not been demonstrated, but is probable. It has been suggested by Hrdlicka that if the argillite man was in possession of the land when the later Indian arrived, there would be found a modification in skull type resulting from the absorption of one race by another. As yet such crania have not been discovered. This is negative evidence, and it is offset by the fact that skulls have been discovered in undisturbed glacial strata that are of wholly different type from that of the Indian. How far we can be guided by craniology alone has yet to be determined, but taking in this case all conditions under consideration, in the Delaware valley, where exhaustive researches have been made (Volk), there is evidence that can scarcely be disputed that man was here to witness the closing acts of the ice-drama — if not its entire progress — and continued to live in this river valley during the subsequent centuries that bring us to the confines of historic time. What relation he bore to the Indian who succeeded him has yet to be determined. The appearances to-day of the soil and underlying sands, each with its imperishable traces of man, suggest continuous occupation of the region, but do not prove it. However this may be, it does not affect the sequence here given of man's career on the Atlantic slope of North America:

A. Paleolithic Man.
B. Post-paleolithic Man.
C. Historic Indian.

The so-called Indian of this continent has been so closely studied, and his handiwork, whether of stone, bone, metal, or clay, scruti-

nized so exhaustively by ethnologists that everything relating to him is familiar to all. But our knowledge is not as definite and free from contradiction as might be wished. Theories beyond count have been elaborately set forth, each claiming to fix finally the career of these people. The literature of the subject is enormous and stands quite as much a monument to our ignorance as to our erudition. That the Indian is a descendant of the man who reached the continent in pre-glacial time or during an immediately succeeding period is in all probability true. That the variations in his degree of culture and all that he has succeeded in accomplishing is due to his environment on this continent; is an unfolding of his faculties uninfluenced except by Nature,— may be accepted as in all probability true of him; even such advanced outreaching toward our own conception of civilization as was found in Mexico, Central America, and in Peru does not call for the incoming of a superior people. The Indian of North America, in possession when the country was invaded by the European, has been denied any significant antiquity, and not a trace of his labors, whether earthwork, shell-heap, or deeply-buried implement has been admitted to possess an age at all suggestive. All the "mounds" have been declared to be of Cherokee origin, and not one dating so far back that the years may not be easily counted. Here the pendulum swung too far toward the craze for modernity. As well confuse the Aztec and the Eskimo. There are mounds and mounds,— mounds proper, the history of which had faded from the traditions of the Indians; and earthworks that were not beyond the capabilities of the various tribal groups or tribes known to the Jesuit fathers who saw the people to such excellent advantage.

It is to the careful examination of our sea-coast shell-heaps that we must look for those evidences of prolonged occupation of the country which admit practically of no dispute. These accumulations of clam and oyster shells in many localities show that they were begun when the shore level was not what it now is; the base of the heaps being now several feet below the water's surface at low tide. These shell-heaps are to be judged by the traces of handiwork found in them and likewise by a careful study of the shells themselves. The implements and pottery have been found in some instances to be of the rudest description, while in others the traces are of workmanship that was reached only in the palmiest days of Indian time. This might prove a snare to the archæologist if all considerations were not kept in view, for not a one-time village site in the land but shows a curious commingling of crude and elaborate implements, weapons, and ornaments; but it has been found — on the North Atlantic coast, at least — that the shell-heaps that are apparently the older are really such from the fact that argillite implements, and no pottery, are found in them. This significance of argillite unassociated with objects of other material has already been pointed out. But more full of meaning than all else is the fact that the same species of mollusk has gradually undergone a change during the time that elapsed between the laying down of the base of the shell-heap and the day of its final abandonment. Evolution is as slow as it is sure, and the change mentioned is alone sufficient to indicate beyond cavil the antiquity of the sea-coast dweller, who must be considered strictly post-glacial, but impressively prehistoric. An overlooked feature of the subject is that of the marked difference in the traces of man found in different village sites scattered over a limited area, as of 10 or 20 square miles. It has not infrequently happened that traces of human occupation have been brought to light wherein nothing but the rudest forms of implements and coarsest grade of pottery occur. Such have been found, too, remote from present watercourses, deeply buried, and the spot still retaining evidences of being heavily forested after the site was abandoned by man. No one can unearth such evidences of one-time human presence without being impressed with their antiquity as counted by years; but of far greater significance is the occurrence of such a village site finally abandoned, overgrown, and buried by drifting sands, and then, when not a vestige of it remained visible, the spot being reoccupied by an Indian of greater skill in handicraft. Exposing the relics of the two occupations and placing them side by side, the difference is eloquent of the lapse of time beyond the skill of pen to picture.

That a family likeness should be traceable among the native races of the Americas is not remarkable and as yet there has been no sufficiency of evidence to lead us to the conclusion that the so-called "Indians" are referable to diverse origins. The cranial differences are of degree only, and when a number of skulls are brought together, the extremes are united by a series of gradations that stamp them all as one in anatomical essentials. Yet, viewing the vast territory as a whole, we find wide differences among these people, differences which may be explained, however, by the wholly dissimilar environment; this not including the strictly boreal people, though their variations from the typical Indian are not, perhaps, so great as has been asserted. The marked feature of the handiwork of Arctic man is skill in carving ivory and very strikingly etching it in such a manner that frequently the fauna of the region and mode of life of the inhabitants are most cleverly depicted. But considering that bone and ivory take the place of stone so largely, and that there is so much enforced idleness during the long Arctic winter, this artistic taste has been most naturally developed. There must of necessity be some occupation, and the artistic instinct is common to all mankind. Whether or not it flourishes — is a vigorous or a stunted growth — is, again, a matter of environment only. The comparatively few stone implements found in the far North are not noticeably well-fashioned, and the majority of their patterns are to be duplicated in the one-time Indian village sites of the temperate regions.

The purported Indian etchings on slate are not as artistic in any instance as those on ivory made within or near the Arctic circle, and it is possible that all or nearly all of them should be ruled out of court. They usually tell too much, when they pass from series of "tally marks" or merely ornamental zigzag lines, which may or may not have had a significance beyond the fabricator's idea of decoration. The tablets from Iowan mounds and the remarkable Lenâpè

stone (q.v.) from eastern Pennsylvania stand out so prominently among the Indian relics of their respective neighborhoods, and especially the latter, that an unqualified acceptance cannot be accorded them. If they were the culmination of artistic effort on the part of the Indians of the central west and Atlantic seaboard respectively, the question arises where are the pictured tablets of lesser degree of merit. There is too great a difference between the notches, straight or zigzag lines and the thrilling scene of battling with a mastodon that finally is stricken by lightning. If all this ever occurred we have not evidence that any Indian of that day had the skill to tell the story in this manner. The same is true of the Iowan tablets. That the Indian had not knowledge of the mastodon we do not claim, for there is every reason to believe that it became extinct in comparatively recent times; probably not more than 25 centuries ago. The conditions under which its bones have been found and the instances of association of human and elephantine bones show that before this country's "autochthonic hunter, Behemoth melted away."

What the Indian was at the time of the Columbian discovery has a distinct bearing on the archæology of the country he occupied, inasmuch as an agriculturist he was in possession of maize and grew it extensively. This plant had become during that time a product of artificiality or cultivated growth, so modified that but for man's care it would be lost. Whatever the plant from which it originated there is no resemblance to it now. To effect such a change calls for an immense lapse of time. Other products of agricultural skill were as carefully grown and the impression that the results of the chase were the main food supply is not a correct one. The researches of Carr on this subject show how methodical these people were as tillers of the soil and that great suffering followed when their crops failed. The Indians did not come to America as agriculturists; of that we can be very sure, and to pass from the hunter-stage of life to that of cultivator of the ground is not conceivable as a sudden transition; but is intelligible as a slow evolutionary process. This development, in no mean stage as finally reached, shows the upward tendency of the Indians in given areas over what is now the United States, and how much beyond the status gained they would have progressed had not European invasion checked their career is conjectural. Herbert Spencer believes they had reached the full limit of their capabilities, but among such a people as these Indians in the 15th century it is conceivable that superior intellects might appear occasionally and such men would have their following. If such men are philosophers and not fanatics, a distinct gain is the result. When it is considered that people with merely a novel view and usually an absurd one become prominent for a day and have a host of applauders, it is not unreasonable to suppose that among the Algonkins or Iroquois there might have risen those who saw the folly of war and set forth convincingly the manifold blessings of peace; who realized the advantages of agriculture over the difficulties attending hunting and so brought into existence a train of thought that would influence the people who gave them a hearing. Attracted first by the novelty of the suggestion, they would later see the logic of the argument, if such existed, and a distinct gain be made. That their growth toward our civilization would ever have been equal to our own is quite improbable, as these people have been as long upon the earth as any other race and America offers opportunities for intellectual growth equal to Asia or Europe. What does appear is that the upward growth was in existence when the blight of European contact fell upon them. Certainly the savage of ten thousand years ago was far lower in skill, in handicraft, and culture generally than the men who witnessed the landing of the Norsemen. Then, or about that time, a fatal scourge seems to have raged along the Atlantic seaboard and the natives suffered a serious check, the result of which appears to have lowered their status, as smallpox and syphilis, introduced by Europeans later, largely decimated their numbers. The Indians for a time were driven to the dire necessity of daily struggle for bare existence, and many of the better things of which they were capable fell into disuse. So, at least, it seems most rational to explain the fact that these people, when European contact became permanent, were not what they had been. They had not been able wholly to recover from one disaster before another overtook them; the last, Spanish, French, and English invasion, proving as destructive as fire upon the dry prairie.

The accounts of what the Jesuit fathers saw and the records of Kalm, Loskiel, Hæckwelder, and many others, make no mention of many forms of implements, ceremonial objects, and talismans, that are now familiar objects in all considerable collections of Indian antiquities; but the simpler forms, as the grooved axe, the polished celt, the arrow-head, flake-knife, and pottery are not only referred to definitely, but the method of manufacture given in considerable detail. Their hunting and agriculture are made plain, and we know with what tools they sought their game and tilled the soil, and more prominent than all else, the culture of tobacco, and the pipe in which it was burned, figure in the pages of the early travelers. Not less conspicuous as objects were more than one form of wrought stone implements to which no reference is made. It is inconceivable that they were successfully hidden, and we can only conclude that they had passed wholly out of use. Assuming that all the products of the Indian's skill in shaping stone, of which we now know nothing, were wholly in disuse and either intentionally hidden or effectually lost, it is strange that the pioneer explorers should have had so little of the archæological instinct as not to have detected traces of them. Had more interest been taken in the Indian's physical welfare, which was important, and less in his spiritual condition, which needed no repairs, we should not now be groping in darkness as to the origin and antiquity of the original, if not autochthonous American.

With so great an extent of country and such diverse physical and climatic conditions, it is obvious that what were originally one people, should by force of environment become widely differentiated in habits of life, and what are now the almost tropical regions of Arizona, New Mexico, and Southern Colorado have been long peopled with Indians that superficially

differ widely from those of the more northern regions. Their cliff dwellings, rock shelters, and well-built permanent dwellings other than those on the faces of cliffs; their pottery, which they had learned to color; their weaving, basket-making, and skill in stone chipping and polishing, all point to a distinct advance over the more northern nomadic tribes. It is practically demonstrated, in the judgment of those who have most exhaustively explored this southwestern region of the United States, that when the country was first occupied by the ancestors of the present Pueblo Indian, the physical conditions and climate were more favorable for human occupation than at present; a fact that has its significance, for the antiquity of man in America is one that has been long disputed; at least an antiquity at all comparable to that of man in Europe. Wandering along our Atlantic coast and laboriously picking from the accumulated shells that have almost hardened into rock, trifling potsherds or a rude arrow-point; or inland, walking over a newly-ploughed field, we gather a grooved stone axe, a celt, spear-head, arrow-point, skin-scraper or a drill; some one or two or perhaps all of these in the course of a morning, we are enabled at best to picture man in but an humble way and think of him as almost one with the wild beasts of the forest on which he preyed — an erroneous, but common impression — then, transplanted quickly to the vast southwest, note the substantial dwelling and skilful products in many lines, it is, at first, difficult to think that these people are but as branches of the same tree. The contrast is impressive and by just so much is it misleading. Step by step the gradations may be traced and when familiar with the handiwork of early man everywhere in North America, the relationship is quite apparent. The need of foreign influence to produce the differences, impressed here and there and again and again, is not apparent.

Mexico and Central America present problems that are not yet solved. Here we are brought face to face with what may be dignified as a real civilization, and so far as its genesis and continuance have been determined, it is essentially a thing of itself and points to no influences other than those that the country might exert. That a foreign element gained lodgment here and through intellectual superiority gained control over and finally absorbed a pre-occupying people has not been demonstrated. So far as we now know of it, it is not a civilization beyond the reach of a native American race. All that is in it that resembles the culture in other continents is far more likely to be coincidence than a transplantation. That essentially the same ideas in given lines may independently arise is beyond dispute. So much more impressive is all that remains of ancient Mexican centres of population that attention has been called to the subject for more than a century and the literature of the subject is enormous, and not free of the curse of undue haste in reaching a conclusion. The Aztec has not been shown to be other than an American Indian, but one advanced beyond the "hunter stage" and so with a fixed habitation. He dwelt where his forefathers had lived and so a more rational, that is, truthful form of tradition was preserved. They were mechanics and artists. They "made useful implements and weapons and high-grade ornaments and jewels from stones, obsidian, and metal (copper, tin, lead, silver, gold); made paper and dyes and were far advanced in weaving, embroidery and feather-work." (Hrdlicka.) They knew well the properties of clay and so ceramic skill was highly developed. With these accomplishments, it is not to be wondered at, that they were also skilled in architecture and erected not dwellings merely, but temples on an elaborate scale and carved their surfaces in most intricate manner. The advanced artisan is always an aspirant and not satisfied, as he might well be, with the acquirements of reasonable creature comfort; in this instance of the Aztec, he devised an intricate form of government and formulated a religion, polytheistic and including "the cult of the sun, moon, and stars; but with this there was a well-defined belief in a single Supreme Deity." (Hrdlicka.) This Aztecan civilization was not alone in America. The Mayans of Yucatan were equally advanced as architects, as artisans, and with society established on an elaborate and intricate basis. If their records have been read aright, they reach back for some seventy-five or more centuries, and granting this as approximating the truth, and claiming the culture existing as an indigenous growth, the date of man's appearance on the continent is carried so far into the past that we must reckon by centuries and not by years. Pure-blooded Aztecs still survive, but the glory of their culture as it blossomed in pre-conquest times, is a matter of history. How great, how far comparable this civilization was to our own can be judged by the exhaustive studies of Madam Zelia Nuttall, in her work, 'The Fundamental Principles of Old and New World Civilizations' (Peabody Museum Memoirs 1901). There is nothing suggestive of the "Indian" as we know him in all these pages. Astronomy, mathematics, and abstruse philosophical disquisition are dealt with and we find, not unnaturally, that in striving to compass the unknowable, they were led to the most extreme cruelty through that anthropomorphic idea of Deity which universally has proved a curse to mankind. The conclusion reached by Mrs. Nuttall is directly the opposite of what has been held in this article as almost if not quite demonstrable; the home, origin, and growth of what has been revealed by archæological research. She writes: "I can but think that the material I have collected will also lead to a recognition that the role of the Phœnicians, as intermediaries of ancient civilization, was greater than has been supposed, and that it is imperative that future research be devoted to a fresh study and examination of those indications which appear to show that America must have been intermittently colonized by the intermediation of Mediterranean sea-farers."

Southward, when the adjoining continent is reached, we find in the vast plains, forests, and following the wonderful rivers of that region, savages that have not as high a standing as those of the temperate regions of North America. The struggle for existence has been, in the tropics, and is, too keen to give opportunity to a mental growth not directly concerned with the bodily passions and demands. Above all else, the savage must eat, and if the food supply

is to be had without effort, the result is bodily inactivity and mental stultification. If the food required must be struggled for, then the body only is excited to vigor, and food obtained, the body is too fatigued to follow physical exertion by mental. This is the result in the extremes of tropical conditions and it is not surprising that man shows to more advantage as the climate becomes more temperate. Mind and body seem then to have more equal chance and the same unevenness of development is found among South American Indians that originally obtained in North America. The differences are those that the different physical features of the country suggested. As Mexico stands to the country north of it, the favored spot wherein flowered and fruited the native civilization of that continent; so in Peru, we find a people who abandoned the more primitive features of a nomadic life, and establishing cities, organized government, society, gave such attention to art, agriculture, and skill in varied handicraft, that they stood apart, finally, from the other peoples of South America. Compared with the advanced civilization of to-day it may seem crude indeed, but if we take their products of handicraft separately into consideration, we shall find that they made most excellent thread and dyed it so honestly, that to-day, many a fabric a thousand or more years old has not lost its brilliancy of color. They were honest workmen as well as artists. It has often been asked would this culture in the interior of Peru have gone on developing, had not it been snuffed out by a really as savage but more powerful a people. It cannot be determined, but as civilization is merely evolution, there is no logical reason why the potter in Peru should not finally have vitrified and glazed his wares, and the metal workers have wrought even greater wonders with the product brought to them by miners who knew their work. Peruvian products in pre-Columbian time, never found a foreign market, but it is rash to say they never would have found it, had they not been molested and their career destroyed for all time by the infamous invader.

Whether in North, Central, or South America, there were centres where things higher than mere animal wants found chance to flourish and the upward growth toward rational rather than mere physical man took place, and all about these centres, roamed those out-lying people, who were not degenerates, but the as yet unadvanced descendants of that original people of the early stone age to whom it fell to populate these two continents. See also MOUND BUILDERS.

Bibliography.— The bibliography of American archæology is more extensive than comprehensive and much more theoretical than practical. The 'Smithsonian Contributions to Knowledge' (Washington, D. C., 1847–1900) contain many important monographs; also the 'Annual Reports' of the same institution. The volumes of the 'Antiquarian Society of Worcester,' Mass., of the now non-existent American Ethnological Society, also, are valuable; likewise the 'Annual Reports of the Regents of the State University,' Albany, N. Y. The Bureau of Ethnology, Washington, D. C., has issued an annual volume of inestimable value for many years; and the publications of the Peabody Museum of Archæology, Cambridge, Mass., and certain of the bulletins of the American Museum of Natural History, New York, are authoritative and necessary for a full understanding of the subject. The separate works that have been published are of less importance. Those prior to 1850 are purely of a speculative character. Of later date, the works of Brinton are of most importance; notably his 'American Race'; 'Essays of an Americanist'; and 'Notes on the Floridian Peninsula.' Of equal importance is Bancroft's 'Native Races of the Pacific Coast.' See also, Dellenbaugh, Moore, Jones, and Mercer, for résumé of subject covering North America, Florida, the Southern States, and valley of the Delaware River, in the order named.

Mexico.— Kingsborough 'Antiquities'; Mayer 'Mexico as It Was and Is'; Humboldt 'Vues des Cordillères'; and the publications of Zelia Nuttall in the series issued by Peabody Museum, Cambridge, Mass., notably 'The Fundamental Principles of the Old and New World Civilizations.' See also Stephens, 'Yucatan.'

Peru.—Transactions of the Ethnological Society of London; biennial reports of International Congress of Americanistes; von Tschudi 'Peru.'

Brazil.— Bates 'Naturalist on River Amazons' (1863); Agassiz 'Journey in Brazil' (1868); Kidder and Fletcher 'Brazil and Brazilians'; R. F. Burton 'Explorations in Highlands of Brazil (1869).

Patagonia.—Dobrizhoffer 'Abiponer' (1822); Muster's 'At Home With the Patagonians'; and for South America generally, transactions of learned societies in Europe,— German, French, and English.

CHARLES CONRAD ABBOTT, M.D.,
Archæologist.

Archæology, Christian. See CHRISTIAN ARCHÆOLOGY.

Archæopteryx, är'ke-ŏp'tĕ-rĭks, an extinct bird exhibiting many reptilian characters, especially in having jaws provided with teeth and a long tail of many vertebræ; and it constitutes a link between birds and reptiles. It lived during the Jurassic period, and is by far the most ancient bird known. Its distinctness from all other birds is expressed by placing it by itself in a separate sub-class, the Archæornithes birds are the rarest of fossils, and this one is known only from two skeletons and a single feather, all preserved in the lithographic limestone quarries of Solenhofen, Bavaria. The skeletons, one in the British, the other in the Berlin Museum, are wonderfully well preserved in the fine smooth-grained stone, and have the impressions of the feathers in their natural position. They show that the Archæopteryx had short wings with primary and secondary feathers arranged much as in modern birds; but the bones of the wing are not so specialized for their peculiar use as in modern birds; the metacarpal bones are separate, and the digits free and complete, each with a claw on its tip, while in modern birds the first and third digits are rudimentary and the metacarpals fused into a single bone. The long tail of 23 separate vertebræ has the feathers arranged in pairs springing from the sides of each vertebra except toward the tip; in modern birds the tail-feathers spring from a triangular bony plate at the end of the short

rudimentary tail. (See BIRDS.) The teeth are like those of many lizards, sharp, conical, each set in a separate socket, and there is no horny bill as in modern birds.

The extinct Dinosaurs are the reptiles which come nearest to Archæopteryx, and it is probable that they are descended from a common stock, the ancestors of the birds becoming arboreal and acquiring rudimentary wings to assist them in leaping from tree to tree. A somewhat analogous case is seen in the fold of skin and hair which the modern flying squirrels have developed for the same purpose; if further developed and specialized this would enable them to accomplish true flight. In Archæopteryx the wings are short and the attachments for the breast muscles (those chiefly used in flight) are small in comparison with those of modern birds, so that the creature must have had very limited powers in this direction.

Archangel, ärk-ān'jĕl, a seaport, capital of the Russian government of same name, on the right bank of the northern Dwina, about 20 miles above its mouth in the White Sea. The port is closed for six months by ice. Archangel, founded in 1584, was long the only port which Russia possessed. Pop. 21,930. The province contains 331,490 sq. miles; pop. 348,500.

Arch'angel, an angel of superior or of the highest rank. They are seven in number, of which Michael, Gabriel, and Raphael are mentioned in Scripture.

Archbald, Pa., borough in Lackawanna County, 10 miles northeast of Scranton, on the Delaware & Hudson and the New York, Ontario & Western Railroads. It was first settled by Welsh miners in 1831 and is to-day essentially a mining town. It has 5 churches, 6 schools, and several imposing public buildings. Two silk mills give employment to 350 persons. Over 3,500 men and boys are employed in coal mining. Population (1890) 4,032; (1900) 5,394.

Archbishop, ärch'bĭsh'ŭp, a chief bishop. The attentive reader of the Acts of the Apostles, noting that nearly the whole missionary energy of St. Paul was expended upon the cities and chief towns rather than on the villages and the country districts, will be prepared to learn that there were flourishing churches in the leading centres of population, while, as yet, nearly all other parts remained pagan. So strong, however, was the evangelistic spirit prevailing, that a number of younger and less powerful congregations were called into being. The pastors of these new churches being called bishops, that term no longer appeared a dignified enough appellation for the spiritual chief of the mother church, and, about A.D. 340, the Greek title of *archiepiscopos* was introduced

An archbishop is often called a metropolitan. He exercises a certain supervision over the bishops of his province, who are called his suffragans; convenes and presides over them in provincial councils, receives appeals against their decisions in matters of discipline, and, in the event of the death of one of them, provides for the administration of the dioceses. In the United States, the Roman Catholic Church is the only one which has dignitaries of this rank, and in 1900 the entire country comprised 14 archdioceses, Baltimore, as the first established see, having the dignity of primacy.

In England the early British churches were, in large measure, swept away by the Anglo-Saxon invaders, who were heathens, and the country consequently required to be reconverted. The great southern centre from which this was done was Canterbury, then the capital of Kent, where King Egbert gave Augustine, the chief missionary, a settlement. In the north, York, the chief town of Northumbria, where King Edwin built a shrine for Paulinus, became the great focus of operation for that part of England; hence the two archbishoprics now existing are those of Canterbury and of York. The prelate who occupies the former see is Primate of all England, while his brother of York is only Primate of England, the superiority of the see of Canterbury, long contested by that of York, having been formally settled in A.D. 1072. The former is the first in dignity after the princes of the blood; the latter is not second, but third, the Lord Chancellor taking precedence of him in official rank. In Ireland the same distinction holds for Armagh and Dublin. When the Catholic hierarchy was established in England in 1850 Westminster was constituted the metropolitan see.

Archdale, ärch-dāl, **John,** American colonial governor: b. Buckinghamshire, England, probably about 1635. Ferdinando Gorges, the last proprietor of Maine, married his sister Mary in 1660, and in 1664 sent him to Maine to set up Gorges' government afresh in opposition to Massachusetts, under whose protection the settlements there had placed themselves. (See GORGES.) They resisted Archdale so fiercely that the next year he sailed for home, entirely baffled. In May 1681 he acquired a dubious title to a share in the proprietorship of the Carolinas, and in 1682 the proprietors commissioned him to come over and receive their rents from "Albemarle" (North Carolina). He was there by 1683, with the intention of settling permanently (as his daughter did) — perhaps drawn by a liking for the Quakers in the colony, he having been converted by George Fox. A few years later, however, he returned to England, and was one of the chief managers of the proprietary affairs. In 1688 he appears on depositions in the Gorges matter, private claims being still unsettled; but there is no evidence that he visited Maine again. In 1694, the Carolina proprietors needing some manager on the spot he was induced to become governor of South and North Carolina by the title of "landgrave" and the attendant barony of 48,000 acres; but it was not till 17 Aug. 1695 that he assumed the government at Charleston, and he retained it but a year, then turning it over to a deputy and returning to England again. The complimentary address of the Assembly on his departure has been taken literally as a proof of influential and pregnant statesmanship; but in fact he dissolved his first Assembly in haste from a quarrel over abatement of quit-rents, compromised with the second, left the Huguenots unenfranchised and the unsatisfactory Indian trade as it was and made no strong impress. His spirit was good, however: he treated the Indians with humanity and modified some hard restrictions on them, drew up a militia act (into which the Assembly unanimously re-

fused to put a clause exempting the Quakers), and established a bureau of public charities.

He is also credited with having introduced rice culture into the Carolinas, through a bag of rice which a merchant vessel brought from Madagascar and he distributed among his friends.

In 1698, elected a member of Parliament, he refused to take the oath but only to affirm, and was not permitted to take his seat. In 1707 appeared 'A New Description of that Fertile and Pleasant Province of Carolina,' by him, a vindication of his administration, of little value except for some original documents.

Archdeacon, ärch'dē'kŭn, an ecclesiastical dignitary next in rank below a bishop, who has jurisdiction either over a part of or over the whole diocese. He is usually appointed by the bishop, under whom he performs various duties, and he holds a court which decides cases subject to an appeal to the bishop. The dignity is still maintained in the Anglican, but not in the Roman Catholic Church, the canons or rural deans exercising the same functions as archdeacons.

Archduke, ärch'dūk', a duke whose authority and power is superior to that of other dukes, a title in the present day assumed only by the princes of the imperial house of Austria. In France, in the reign of Dagobert, there was an Archduke of Austrasia; and at a later period, the provinces of Brabant and Lorraine were termed archduchies. The Dukes of Austria assumed the title of archduke in 1156; but the dignity was not confirmed till 1453.

Archegosaurus, är'ke-gō-sō'rŭs, a fossil saurian reptile, found in 1847, in large concretionary modules of clay-ironstone, from the coal field of Saarbrück. Four species have been described. Prof. Owen makes it a connecting link between the reptile and the fish, and on these grounds: it is related to the salamandroid-ganoid fishes by the conformity of pattern in the plates of the external cranial skeleton, and by the persistence of the chorda dorsalis, as in the sturgeon, while it is allied to the reptiles by the persistence of the chorda dorsalis, and the branchial arches, and by the absence of the occipital condyle or condyles, as in Lepidosiren, and by the presence of labyrinthic teeth, as in Labyrinthodon, which, however, also ally it to the ganoid Lepidosteus. See STEGOCELPHALIA.

Archelaus, är'ke-lā-ŭs, the name of several personages in ancient history, of whom we need mention only Archelaus the son of Herod the Great. This prince received from Augustus, with the title of Ethnarch, the sovereignty of Judea, Samaria, and Idumea. His reign is described as most tyrannical and bloody. The people at length accused him before Augustus, who, after hearing his defense, banished him in A.D. 10 to Vienne, in Gaul, where he died. To avoid the fury of Archelaus, Joseph and Mary, with the infant Jesus, retired to Nazareth.

Archenholz, är'ʜen-hōlts, **Johann Wilhelm von,** a German historian: b. 5 Sept. 1743; d. 28 Feb. 1812. He took part in the closing campaigns of the Seven Years' war and retired as captain, 1763; traveled extensively in Europe, lived in England the greater part of 1769–79, and settled in Hamburg in 1792. His book on 'England and Italy' (1785), extensively translated, obtained a phenomenal success. A sequel to it was 'Annals of British History' (1789–98, 20 vols.). His 'History of the Seven Years' War' (1789; augmented 1793, 13th ed. 1892) is still the most popular account of that war.

Arch'er, Belle, actress: b. Easton, Pa., 1860; d. 1890. Her maiden name was Arabella S. Mingle; married Herbert Archer, 1880, and was divorced from him, 1889. She made her début in Washington, D. C., with Wm. Florence in 'The Mighty Dollar,' and later played leading parts in 'Pinafore,' 'Hazel Kirke,' 'Lord Chumley' (1888), and Tennyson's 'Foresters.' For a time she was leading woman with Sol Smith Russell.

Arch'er, Branch T., Texan revolutionist: b. Virginia, 1790; d. Texas, 22 Sept. 1856. He studied medicine in Philadelphia, practised many years in Virginia, and was repeatedly a member of the legislature. In 1831 he removed to Texas, and was one of the leaders in preparing for the revolution determined upon far in advance of the actual crisis. On 3 Nov. 1835 he presided over the celebrated "consultation" of the American settlers concerning independence, and immediately after was one of three commissioners — the others being Stephen Austin and N. H. Wharton — to solicit aid from the United States. The next year he became speaker of the House in the first Texan Congress; and he was secretary of war for Texas 1839–42, when bodily infirmity compelled him to retire from public life.

Arch'er, Frederic, organist and musical director: b. Oxford, England, 1838; d. Pittsburg, Pa., 1901. Educated at Oxford, London, and Leipsic, and held important positions as organist in Oxford, London and Glasgow, 1852–79. Organist Plymouth Church, Brooklyn, N. Y., 1880–85; conductor Boston Oratorio Society, 1887; founded Pittsburg Symphony Orchestra, 1896; organist Church of the Ascension, Pittsburg, 1899–1901. He gave recitals and lectured on musical subjects throughout the United States and Canada. Founded and edited 'The Keynote' (1885).

Arch'er, John, physician: b. Harford County, Md., 6 June 1741; d. there, 1810. Graduated at Princeton, 1760, and in 1768 received from the Philadelphia Medical College the first medical diploma issued in America. He raised and commanded a military company during the Revolution, served several years in State Legislature, was a presidential elector in 1801, and member of Congress 1801–7. He made several discoveries in medicine which have been adopted by the profession.

Arch'er, Thomas, an English novelist and essayist. His works deal with the conditions of the working classes and with social evils. Among the best known are: 'A Fool's Paradise' (1870); 'Profitable Plants' (1874).

Arch'er, William, an English author and critic: b. Perth, Scotland, 23 Sept. 1856. Educated at Edinburgh University; became barrister, Middle Temple, 1883. Went to London 1878, became dramatic critic of the *Figaro,* 1879–81, and London *World* since 1884. In 1899 he visited the United States to study American theatres. He has edited and translat-

ed Ibsen's 'Prose Dramas' (5 vols.); and with his brother translated Ibsen's 'Peer Gynt.' He has written 'Life of Macready' (1890); 'English Dramatists of To-day' (1882); 'The Theatrical World' (5 vols. 1893–97); 'Study and Stage' (1899); 'America To-day' (1900); 'Poets of the Younger Generation' (1901); 'Masks or Faces: a Study in the Psychology of Acting.'

Arch'er-fish, a fish reputed to be able to shoot drops of water from its mouth at insects in the air above, thus bringing the insects down where they can be seized. The name is most frequently applied to a single species, *Toxotes jaculator*, a fish six or seven inches long, a native of Java and the neighboring islands, which represents an aberrant group of chætodonts, or coral fishes (q.v.). This, however, is an error of identification, the true fish with this habit being a related small coral fish (*Chelmon rostratus*) of India. This genus has its mouth extended into a tube-like snout, forming a sort of nozzle. When it perceives an insect perched on a plant over the water, it swims to within a distance of from four to six feet, and then with surprising dexterity will eject a single drop of water with so true an aim as to knock the insect into the water where it is instantly seized. Captives will do this in a tank or aquarium; whereas experiments show that the Toxotes never does such a thing for which its mouth is entirely unfitted.

Arch'ery. Ages after the bow and arrow had disappeared in general use from Europe and many other countries, it was the universal arm both for war and sport in the Americas, from Patagonia to the Arctic Circle, and its use lingered on the borders of advancing civilization till within the memory of thousands living. It may indeed be considered the most characteristic American weapon, yet the practice of archery as a recreation is limited. A few societies of Toxopholites exist and hold monthly meetings and annual contests. The principal clubs are in the neighborhood of Washington, D. C., and of Cincinnati.

A faithful band, too, of whom the late Maurice Thompson, the author of 'Alice of Old Vincennes,' was the exponent, have continued into this 20th century to take the bow and arrow into field and forest, and to live while in camp by the product of their skill in its use. Several charming pen pictures may be found in the pages of 'Scribner's,' 'Harper's,' 'Outing,' and the 'Badminton' magazines, relating their hunts after turkeys, herons, wild duck, wood-duck, and squirrels, and even fish, in Florida, Georgia, Illinois, Indiana, and other States. For practical purposes, however, the attention may be confined to archery as popularly understood: that is, shooting at the target as a recreation and to acquire skill. This form of its use continued long after gunpowder had become common: in fact the first book of instruction in archery, that of Roger Ascham, the teacher of Lady Jane Grey, and professor of Greek at Cambridge, 'Toxophilius, or the Schole of Shooting,' was published in 1571, when the bow had practically become obsolete as a weapon of offense. The bow used for recreation is the long-bow and not the arbalest or cross-bow which was used by William Tell. That style of the bow was never popular in England. As gunpowder came more and more into use in sports, the interest in the bow and arrow faded. About the year 1760 the possibilities of archery as a builder up of the body and the eye-sight were rediscovered, and from thenceforward it had a lusty growth and has always had a considerable following of devotees both in England and America. Bows are made either of one piece of wood, or two or more strips glued together, preferably of yew. A man's bow is about six feet in length, and a woman's some half a foot shorter. A man's bow requires a pull of from 40 to 50 pounds, a woman's about half that amount. The distance shot varies with the kind of contest: a Potomac round consists of 24 arrows at 80 yards, 24 at 70 and 24 at 60. A double Columbia round of 48 arrows at 50 yards, and 48 at 40. A double York round of 144 arrows at 100 yards, 96 at 80 and 48 at 60. A double National round of 96 arrows at 60 yards and 48 at 50, and a double American round of 60 arrows at 60 yards, 60 at 50 and 60 at 40. The arrow's shape and feathering is a matter of personal inclination. The targets are four feet in diameter, made of banded straw with a canvas front painted in five concentric rings, the centre gold, then red, blue, black and white; the value in counting shots being, respectively, 9, 7, 5, 3 and 1. There are in the National meet also competitions for longest flight and annual team competitions of 96 arrows at 60 yards for men and 96 arrows at 50 yards for women.

Arch'es Court, the chief and most ancient consistory court, belonging to the Archbishopric of Canterbury, for the debating of spiritual causes. It is named from the church in London, St. Mary le Bow, or Bow Church (so called from a fine arched crypt), where it was formerly held.

Arch'ibald, Sir Adams George, Canadian statesman: b. Truro, Nova Scotia, 18 May 1814; d. Halifax, 14 Dec. 1892. He was secretary of state for the Dominion of Canada, and lieutenant-governor of the Northwest Territories, and Manitoba, later; and later held the same office in Nova Scotia. He was knighted in 1885.

Archidamus, är'kĭ-dā'mŭs, the name of several kings of Sparta. I. The son of Anaxidamus, who lived during the Tegeatan war, which broke out soon after the termination of the second Messenian war, in the year 668 B.C. II. The son of Zeuxidamus, and succeeded to the throne in the year 469 B.C. In the fifth year of his reign there was an earthquake in Laconia which almost destroyed Sparta. In that trying period the foresight of Archidamus probably saved the surviving citizens from being massacred by the Helots. In the discussions at Sparta and Corinth, which preceded the rupture with Athens, he acted a prominent part, and always as the advocate of peace and moderation. He survived the outbreak of the Peloponnesian war about five years, during which time he had the conduct of three expeditions against Attica and one against Platæa. Archidamus died in the 42d year of his reign, 427 B.C. III. Son of Agesilaus II. While yet a boy he prevailed on his father to pardon Sphodrias, who had dared to make an irruption into Attica at a

time of profound peace. In 371 B.C. he was sent to the relief of his countrymen who had been vanquished at Leuctra. In 367 B.C. he defeated the Arcadians and Argives in what the Spartans termed the «scarless battle,» because they had won it without the loss of a single man. Archidamus III. appears to have been a warlike prince, but he was neither a great general nor a great statesman, and makes but a poor figure in either capacity after such kings as his father and grandfather. IV. Son of Eudamidas I. and grandson of Archidamus III., was king of Sparta in 296 B.C. V. Son of Eudamidas II. Archidamus V. was the last king of the Eurypontid race that reigned in Sparta. When he was killed the rights of his children were disregarded and his crown was given to a stranger.

Archil, är'kĭl, or **Orchil,** ôr'kĭl, a coloring matter obtained from various kinds of lichens, the most important of which are the *Roccella tinctoria* and the *R. fuciformis*. The *Lecanora tartarea*, or cudbear, is another of the same nature; orchella-weed and dyer's-moss are common names for them. The *R. tinctoria*, or archil plant proper, is abundant in the Canaries and Cape Verde Islands, and in the Levant; the *R. fuciformis* also grows chiefly in warm climates, as the coasts of Africa (Angola) and Madagascar. The lichens, which are chiefly collected from rocks near the sea, are cleaned and ground into a pulp with water, after which some ammoniacal liquor is added, when the coloring matter, red, violet, or purple, is evolved and falls to the bottom. The red coloring matter of *Lecanora tartarea* produces litmus when lime or an alkali is added. Archil has a beautiful violet color. It is used for improving the tints of other dyes, as from its want of permanence it cannot be used alone.

Archilochus, är-kĭl'ō-kŭs, a Greek poet, classed by Cicero with Homer and Sophocles: b. in the Island of Paros, flourished between 720 and 660 B.C. While a resident of Thasos, he incurred disgrace by throwing away his shield in a battle. He was the inventor of iambics. His terrible invective is said to have caused several suicides. A hymn to Hercules was the most esteemed of his poems, and used to be sung three times in honor of the victors at the games.

Archimandrite, är'kĭ-măn'drīt, in the Greek Church, an abbot or abbot-general, who has the superintendence of many abbots and convents.

Archimedes, är'kĭ-mē'dēz, one of the most celebrated among the ancient physicists and geometricians; b. at Syracuse, about 287 B.C. Though, according to some accounts, a relation and certainly a friend of King Hiero, he appears to have borne no public office, but to have devoted himself entirely to science. We cannot fully estimate his services to mathematics for want of an acquaintance with the previous state of science; still we know that he enriched it with discoveries of the highest importance, upon which the moderns have founded their admeasurements of curvilinear surfaces and solids. Euclid, in his Elements, considers only the relation of some of these magnitudes to each other, but does not compare them with surfaces and solids bounded by straight lines. Archimedes has developed the propositions necessary for effecting this comparison in his treatises on the sphere and cylinder, the spheroid and conoid, and in his work on the measure of the circle. He rose to still more abstruse considerations in his treatise on the spiral, which, however, even those acquainted with the subject can with difficulty comprehend. Archimedes is the only one among the ancients who has left us anything satisfactory on the theory of mechanics, and on hydrostatics. He first taught the principle "that a body immersed in a fluid loses as much in weight as the weight of an equal volume of the fluid, and determined, by means of it, that an artist had fraudulently added too much alloy to a crown which King Hiero had ordered to be made of pure gold. He discovered the solution of this problem while bathing; and it is said to have caused him so much joy, that he hastened home from the bath undressed, and crying out, Eureka! Eureka! "I have found it; I have found it!" Practical mechanics, also, received a great deal of attention from Archimedes. He is the inventor of the compound pulley, probably of the endless screw, etc. During the siege of Syracuse he devoted all his talents to the defense of his native country. Polybius, Livy, and Plutarch speak in detail with admiration, and probably with exaggeration, of the machines with which he repelled the attacks of the Romans. They make no mention of his having set on fire the enemy's fleet by burning-glasses,— a thing which is in itself very improbable, and related only in the later writings of Galen and Lucian. At the moment when the Romans, under Marcellus, gained possession of the city by assault, tradition relates that Archimedes was sitting in the market-place absorbed in thought, and contemplating some figures which he had drawn in the sand. To a Roman soldier who addressed him, he is related to have cried out, «Disturb not my circle!» but the rough warrior little heeded his request, and struck him down. The conquest of Syracuse is placed in the year 212 B.C. On his tombstone was placed a cylinder, with a sphere inscribed in it, thereby to immortalize his discovery of their mutual relation, on which he set particular value. Cicero, who was appointed quæstor over Sicily, found this monument in a thicket which concealed it. Of the works of Archimedes there are extant a treatise on ‹Equiponderants and Centres of Gravity,› in which the theory of the lever and other mechanical problems are treated; on the ‹Quadrature of the Parabola›; on the ‹Sphere and Cylinder›; on the ‹Dimensions of the Circle›; on ‹Spirals›; on ‹Conoids and Spheroids›; the ‹Arenarius,› a speculative treatise intended to refute the popular notion that the number of grains of sand on the seashore is infinite by showing that a definite number might be assigned to a quantity of grains sufficient to fill the sphere of the fixed stars, remarkable as containing an anticipation of the modern discovery of logarithms; on ‹Floating Bodies›; a treatise called ‹Lemmata,› of doubtful authenticity, on plane geometry. A very complete and splendid edition of the works of Archimedes issued from the ‹Clarendon Press,› at Oxford, in 1792. Other editions appeared in 1881, and 1897.

Archimedes, Principle of. See ARCHIMEDES.

Ar'chime'des' Screw, a machine invented by Archimedes while studying in Egypt. Observing the difficulty of raising water from the Nile he is said to have designed this screw as a means of overcoming the obstacle. It consists of a pipe twisted in a spiral form around a cylinder, which, when at work, is supported in an inclined position. The lower end of the pipe is immersed in water, and when the cylinder is made to revolve on its own axis, the water is raised from bend to bend in the spiral pipe until it flows out at the top. The Achimedian screw is still used in Holland for raising water, and draining low grounds. The Dutch water-screws are mostly of large size, and are moved by the wind, one windmill furnishing sufficient motive power to keep several screws going at once.

Archipelago, är'kĭ-pĕl'a-gō, a term originally applied to the Ægæan, the sea lying between Greece and Asia Minor, then to the numerous islands situated therein, and latterly to any cluster of islands. In the Grecian Archipelago the islands nearest the European coast lie together almost in a circle, and for this reason are called the Cyclades (Gr. *kyklos,* a circle); those nearest the Asiatic, being farther from one another, the Sporades ("scattered"). (See these articles, and Cyprus; Negropont; Rhodes; Samos; Scio, etc.) The Malay, Indian, or Eastern Archipelago, on the east of Asia, includes Borneo, Sumatra, and other large islands. See Malay Archipelago.

Architecture, skilful, or at least careful, building; and it is in this sense that we speak of military architecture, naval architecture (qq.v.), and the like. In a general sense, building which has been made interesting by artistic consideration, the proportions of the structure having been considered, its details treated in a deliberate way, ornamentation applied whenever practicable, and the whole structure imbued with the artistical spirit. Of course architecture in this sense cannot exist without civilization, and the beginnings of civilization are commonly marked by an artistic treatment of buildings, such as huts for residence and larger cabins for the meeting of a tribe or its chief men. Buildings dedicated to religious purposes always appear early in the advance toward higher civilization: and it is mainly in temples and churches that architectural development appears, in any age. In this article it is intended to describe and analyze the architecture which has given rise to European styles, and those European styles themselves, from the commencement of history until the close of the 19th century. For the architecture of the Far East such as India, Farther India, China, and Japan, and for the primitive architecture of America, see separate headings.

The most primitive races using architecture of which we have any knowledge, are those of the Pacific islands in our own time. In New Zealand especially the large huts have much decorative woodwork combined in an intelligent way to produce a general effect. Again in the islands of Micronesia the larger residences and the buildings of the community are designed according to a very strict and semi-religious tradition.

Now this same kind of tradition, more or less closely united with the pious beliefs of the people and with the teachings of their priesthood, is found to have existed in Egypt at a time not exactly prehistoric, because we are gradually approaching to an accurate knowledge of the dates, but of an epoch not as yet exactly fixed — an epoch at least 5,000 years B.C. From that time on for many centuries the plan of a palace, or of a temple, or of one of those great buildings in which palace and temple seem to have been united, was a thing almost absolutely fixed in advance; and moreover the external ordonnance, the succession of pylons, the colonnaded porches, would be unchanged except as to minor considerations. One temple would have colossal statues backed up by the piers of the façade; another would have a row of columns with enriched capitals and sculptured drums; all these changes would find their explanation in the changing fashion of the time; but the general disposition of the covered buildings alternating with open courts and culminating in a shrine accessible only to the few, would be unchanged. The origin of the forms of Egyptian architecture is undoubtedly to be found in the building with a light skeleton of reeds daubed with mud, but this structure left only its superficial appearance to the stone temples which were to succeed it. In actual building no race was ever more thoroughly skilled in quarrying, cutting, transporting, and combining blocks of limestone, and more rarely of harder rocks. These materials they used chiefly to provide themselves with broad surfaces — sometimes flat, as of a sloping wall, sometimes rounded, in an approximately cylindrical way, as in a huge column; and these surfaces they enriched by sculpture in low relief and especially in that coelanaglyphic relief in which the background is not cleared away; and these reliefs they painted richly in brilliant colors. At a later time and especially for interiors the painting was done upon smooth walls and ceilings, and a whole school of flat pattern designing was developed, equal in effectiveness to any decorative painting of more recent times.

The culmination of Egyptian architectural art is to be found at a very early date. Many persons will think that it never again attained the dignified splendor of that which dates from the 25th century B.C. One thing at least, is certain — technical perfection has never, in any land, surpassed that with which huge blocks of granite, squared and polished and inscribed with complicated patterns, were used in buildings of that time. Still the 17th and 18th dynasties, which are now dated 1610 to 1320 B.C. (Flinders Petrie), will seem to most students the time of the greatest Egyptian architecture, for it was then that the great buildings at ancient Thebes were built, including temples and palaces, where now stand the modern villages of Karnak and Luxor, on the right bank, and, on the left bank, Dahr-el-Medinah and Medinet-Habu, with all the remains of the great necropolis. All of the buildings here named or included by implication were really for residence or ceremonial, excepting the tombs, the interiors of which are of surprising beauty of decoration. The famous Pyramids, whether the great ones of Gizeh, which are the oldest, or the much smaller ones of later times, are not architecture in the æsthetic sense except as they are carefully wrought, the slopes of their sides accurately de-

HATHORIC COLUMN, TEMPLE OF DINDERA

(Restored)

termined, their placing by the points of the compass very precise, and the whole structure invested with a quasi-religious character. Artistic design is hardly to be assigned to them; indeed the great pyramids are nothing but cairns, that is to say, heaps of stone within which a couple of chambers have been carefully laid out; technical excellence is never at fault, and some astronomical knowledge is evident in the placing and shaping of the structure, but this does not constitute artistical building.

The architecture which was contemporary with this in Syria and Mesopotamia is hardly known to us as yet; the results of it are traceable in the buildings of Nineveh, dated the 8th and 7th centuries B.C., but even this has perished so generally that there has been much dispute as to the manner of roofing the palace halls. The decision of recent archæologists is that these halls, long and narrow, and enclosed by walls of unburned bricks but of enormous thickness, were roofed with wagon vaults, also of unburned brick, curious devices being employed to let in the breeze sweeping over the low, flat land bordering the Tigris, while excluding the burning sun. The decoration of these buildings must have been largely by means of sculpture, flat slabs of alabaster which lined the walls being exquisitely carved in low relief with subjects of war and hunting, or of the king doing worship to his gods. Much more massive sculptures were carved in great blocks of limestone for the gate-posts, such as the huge winged lions and winged human-headed bulls of which specimens have been brought to the Louvre and to the British Museum. The characteristic of these palaces was their position upon the flat tops of the somewhat broad artificial terraces paved at a height of 25 or 30 feet above the country around, from which pavement arose the principal rooms of the residential buildings and the more tapering mass of the great temple. These temples were apt to be built with steps, but were otherwise pyramidal in form. They never reached a height approaching that of the Pyramids of Egypt, nor were they of anything like the same solidity of structure, being generally built of unbaked clay in cast blocks, such as we call crude bricks, and faced with burned bricks. Such a structure crumbles into mud or dust when neglected, and the huge mounds along the Euphrates and the Tigris which have been opened and within which the treasures of Babylon and Nineveh have been found, are made up of this debris.

The architecture of ancient Persia dates from about 500 B.C., as far as our knowledge goes. From this time on until the conquest by Alexander, 334 B.C., that ancient Persian art which we call Persepolitan from the famous ruins at the site of ancient Persepolis controlled all that inland country of Asia which lies immediately east and north of Mesopotamia. It was an architecture of terraced palaces and halls of many columns, but the terraces and platforms not being needed in a hilly country, were much lower, evidently serving merely for splendor, as the European palace is often raised upon an architectural basement. The chief value of this art to European students is in the beginning of that wonderful system of decoration by means of colored patterns, both flat and in slight relief, in which for two thousand years the Persians were the masters of the world, teaching the races of Asia as well as of Europe what pattern-making and the application of brilliant colors to a flat surface might produce.

Contemporary with the latest Assyrian work were the beginnings of Grecian architecture, and contemporary with Persian work as above alluded to, came the culminating period of Greece. There had been at a previous time the strange Mykenæan art which cannot be dated with any accuracy, and which is far more Asiatic than Greek, and which as we now know, was more fully developed in Crete and perhaps in Cyprus than in the mainland of Greece. Of this art we have little in the way of permanent buildings. But with the year 600 B.C. the beginnings of the Doric style appear, the quarries of marble and of softer stone are worked in an intelligent way and the round column with the square abacus is used to form colonnades. The temple of those early days was that which it continued to be till the fall of all Grecian civilization came at the close of the classical epoch. It was a shut-up room without windows, divided, when very large, with columns in two rows, and perhaps lighted from above either by sky-lights or by some system resembling that of the mediæval clearstory, but of this we have no knowledge. The great eastern and western doorways were the only means of admitting daylight to which we can certainly point. Only a few temples had a colonnade on every side as had the Parthenon, the so-called Temple of Theseus at Athens and other buildings in Greece and in the colonies. By far the greater number had a portico at one end, the east, or one at each end; the wall of the enclosed chamber or naos (called cella by the Romans) showing at the northern and southern sides between the porticoes at the ends. Of other buildings than temples we know only porticoes, roofed, but open on at least one side. Otherwise we have no knowledge of Grecian buildings. Gate-way buildings (propylaia) were roofed in part but served merely as passageways: when enclosed rooms were attached to them, these are ruined, and we know nothing of their ordonnance. There was also the meeting hall at Eleusis with many columns supporting the roof, but what its interior disposition was we do not know at all. So with dwellings, some little is known of the plan of a Grecian house, but no one has ever a reasonable theory as to its architectural treatment.

The reason why Grecian architecture has obtained such a prodigious hold upon the imagination of Europe is the control which its beauty and refinement, when in their full glory, exercised over the intelligence of the great Roman Empire. From 200 B.C. at least until 350 A.D., all the world which was destined to become European in feeling and much that has not retained that European character, was largely controlled by the great influence spreading from the city on the Tiber; and this influence, so far as it was artistical, was derived in its turn from the cities of Greece. It was the mission of the Roman Empire to spread and perpetuate Hellenism, and it is to that combination of influences that the tradition and the learning of Europe are what they are in contradistinction to that of India, China, and the other ancient lands of Asia. The peculiar charm of Greek art was in its extreme subtlety of proportion, and in the

grace and refinement of its details; but in gaining these advantages it lost variety, movement and life, and deliberately shut itself off from much that is absolutely essential to the modern world. Thus no man can build a house now in the Greek style, because he is absolutely ignorant of what a Greek would have done with a large hall, or with a group of five or a dozen small rooms and passages. He does not know how a Greek would have made a window; he has no knowledge at all of how a Greek would have put one story upon another; in other words, Grecian architecture remains for us as an astonishing piece of perfection of limited range and small adaptability.

The artists and the engineers of the great Roman Empire inherited the Etruscan notion of building with the round arch built of voussoirs or wedge-shaped slabs — a thing never used by the Greeks in architecture. The Roman commonwealth at its commencement was as much Etruscan as Latin, and this use of the vault, together with the free employment of glazed and painted earthenware for the interiors of buildings was perhaps common to both races, but was certainly familiar to the people of Etruria. Helbig points out that the boast of Augustus of "having found Rome a city of brick and leaving it marble" had a more exact significance than appears on the surface, for the Rome of the days of Julius, the Rome which Octavianus must have seen as a child, was really a city of brick houses with terra cotta ornaments. But the Greek invasion had begun earlier than the days of Julius, and he himself was destined to be the great introducer of the refined columnar architecture of Greece into his native city. Augustus and the following emperors and their admirers and followers within and without the Imperial City took up this mode of building with the long rows of marble columns, and from London and the Strait of Gibraltar eastward to the sands of the Arabian Desert, the common style of beautifully ordered pillars carrying roofs light in proportion to the substructure made the cities splendid. The cities of the East were particularly famous for their colonnaded streets, and those of Palmyra, Gerasa and Antioch were unsurpassed except in the Imperial City itself.

The Romans developed also a totally non-Greek system of building with small stones laid in quantities of rather liquid mortar, making of this masonry very heavy walls, which were faced and rendered smooth by brickwork of thin, hard-baked tiles, laid also in mortar. These halls and passages they vaulted in the same materials, and made them solid and immovable. They desired, of course, to combine their great porticoes with their vaulted interiors, and great ingenuity is shown in reaching an approximate success in this matter. See Roman Imperial Architecture.

These two traditions struggled together in the work of small communities, the impoverished states which grew up over the ruins of the Empire. Christian churches had to be built in the East as in the West. It is curious to note that the West took up the colonnaded style and built what we call basilica churches, that is, buildings whose plan is a long parallelogram divided by rows of columns lengthwise through it; while in the East the vault generally prevailed, and gave birth to what we call Byzantine architecture. The fact of this Eastern preference for the vaulted system points to what has been thought the probable origin of the Roman vaulting, namely, in Alexandria and other cities of the Macedonian Empire, as divided into the kingdoms of the Diadochi, the successors of Alexander the Great. No traces of it have, however, been identified. Round and polygonal churches were not unknown in the West. Basilica churches also existed in the East, but very few, and of very early times, the 5th and 6th centuries; but the Byzantine style, based entirely upon vaulting of great boldness, but lighter and far less enduring in appearance than the Roman work, was destined to be, from that time on, the characteristic of Christian architecture of the Levant and also to be the inspiring thought at the bottom of the architecture of the Mohammedan conquerors. The first perfectly realized Byzantine building is also the greatest — the Church of Saint Sofia in Constantinople was finished between 532 and 537 A.D., but partly rebuilt in 563. It may well be thought the most beautiful of churches, but in saying this one has in mind the interior only. All church building, even the latest and richest Gothic, has the exterior for its chief splendor. It is only true that the exterior is more entirely disregarded by the Byzantines and apparently no thought whatever given to the effect of the external shell. The style invented in this way at a single effort (a result not known to have been achieved anywhere else in the history of art) has prevailed ever since over all the lands from the Red Sea northward and even over all the plains of Russia, if we are considering church architecture alone. The more recent buildings of Asia Minor, Armenia, The Caucasus, Moldavia, Greece and Russia to the Baltic, may be without direct reference to Byzantine systems of design so long as they are merely low walled residences, or if larger and built of timber; but the church is everywhere Byzantine. The boundary between this and the Romanesque art of western Europe runs along the eastern frontier of Dalmatia and then eastward somewhere near the Danube; for Hungary is generally western in its church architecture, while the Balkan Peninsula is Byzantine.

The Romanesque of western Europe is a style almost wholly based upon church building and characterized by an effort to be as Roman as possible under changing conditions. From the first the struggle to vault every nave and aisle and sanctuary in the classical Roman way is obvious, but also it is obvious that the small means and the poor skill of the people held them back all the time. Under these conditions there grew up in Italy a Latin style, partly the result of copying classical basilicas and partly of copying the interiors of great Roman houses which had often been the refuge of a poor and timid congregation of Christians. This style is best known also from the churches of Ravenna and the oldest churches of Rome. There was also a Lombard style in the north of Italy, partly the result of the invasion of barbarians, partly of Byzantine invasions coming from the East. Again there grew up slowly the beautiful Pisan style of central Italy: and all these styles may be included in the general term Romanesque.

In the north of Europe nothing earlier than the 9th century is accurately known to us, and even of that epoch the buildings which we know

are few in number and often greatly rebuilt. Such a building is the church at Aix-la-Chapelle in Rhenish Prussia, the cathedral built by Charlemagne himself, but it has been altered out of recognition. There is a conventual church at Hechingen, near Stuttgart, and at Quedlinburg in Prussian Saxony, and these churches are marked by a beautiful system of quasi-classical sculpture with scroll-work and elaborate moldings, and by a system of vaulting with groined vaults very effective but not allowing of very great variety of structure. The vaults are low and narrow, and even under these conditions the history of every great church is a record of constant accidents befalling the vault. The noble cathedral of Speyer, the capital of Rhenish Bavaria, and the church at Gernrode belong to a later period, namely, the 12th century, and of the same time or a very little later are the church of St. Godehard and the church of St. Michael at Hildesheim, the Cathedral of Mainz (Mayence), of Braunschweig (Brunswick), and the Cathedral at Worms. These great churches have held their own, unchanged in important details, since the time of their first building, and but for these and a few more we should not know how interesting and on the whole efficient a style the northern Romanesque could be. On the other hand the churches of middle France are more rich in sculpture. Nothing can exceed the splendor and, in a limited sense, the beauty of such fronts as the Cathedral at Angoulême, and Notre Dame la Grande at Poitiers. The Cathedral at Le Puy has also much beautiful sculpture, but is especially famous for its surprisingly picturesque situation and design, and its very beautiful polychromatic exterior. The Church of La Madeleine at Vézelay, and that of Notre Dame du Port at Clermont, are great steps in the development of the Romanesque churches leading to the Gothic style: and in the far south the churches at Arles, Saint Gilles, and Saint Saturnin at Toulouse, are examples of a rich and brilliant Romanesque quite different in character from anything in the north of France, or in Germany. France has also a great number of domed churches partaking strongly of the Byzantine character.

There is beautiful Romanesque also in England, where the nave of Peterboro and that of Winchester are splendid examples; and in Spain some of the richest churches in Europe are of this style.

The far North — Denmark and the Scandinavian Peninsula — have also beautiful Romanesque, as in the Cathedral of Lund in Sweden; but the characteristic architecture of Norway is a style depending upon wood for its structure and upon elaborate carving for its decoration.

The above considerations bring us to the middle of the 12th century and at this point it becomes necessary to consider the works of the Mohammedan nations, who were following in the main the Byzantine style. Some of the earliest of these Mohammedan churches have a disputed date; thus the famous Mosque of Omar in Jerusalem has always been a point of dispute, some historians putting its structure as early as the beginning of the 8th century. It is known that the early mosques at Cairo, such as that of Ibn Tulun were built in the 9th century. The architecture of a later time is more splendid if less massive and constructional. The Moslem architecture spread east and west in the trail of the conquering armies, and there is a Mohammedan style in India of extraordinary splendor, its chief epoch being between 1180 and 1600 A.D. (See INDIA, ARCHITECTURE OF.) The conquest of northern Africa and of nearly all the Spanish Peninsula gave rise to what we call the Moorish style, never equal in dignity or beauty to the architecture of Cairo and Damascus, but enriched with elaborate but fantastic carving, and also plaster work modeled and stamped, and all richly painted. The most celebrated buildings of this style are the Mosque of Cordova and the Palace of the Alhambra on the hill near Grenada. The tendency of the Eastern mind is seen in rich chromatic decorations, not only in paintings but also in rich enameled tiles with which large surfaces of wall are adorned, and also at least in the wealthier cities, with exquisite inlays of colored marble.

In the middle of the 12th century, the peoples of what we now call France, western Germany, England, and Belgium were building skilfully and intelligently in their Romanesque style, but were still much harassed by the difficulty of the round arched vault. This difficulty was peculiarly great when it became necessary to carry a deambulatory like an aisle around a semicircular apse. All the ingenuity of the builders was put into this, and without perfect satisfaction to them. There was then taken up a device which seems simple and rather obvious, the device of springing a narrow arch of very solid material from one pier or column or corbel to another, and building as many such arches as the space to be filled made necessary — then filling up the resulting spaces with light vaulting which rested upon these cut-stone arches. To take the simplest case, if a parallelogram of 900 square feet were to be filled, it would take a fairly good builder to make a groined vault stand; but any beginner could build four narrow arches on the four outlines of the square and two other arches diagonally dividing it into four panels, each of about 200 square feet. Anybody could fill one of these with a thin shell of vaulting: and it is out of this simple device that there grew the great Gothic architecture. The diagonal arches met in the middle at a kind of boss. We may then consider those diagonals as consisting of four half arches meeting in the middle. Looked at in that way, irregular spaces could be vaulted without trouble and the plan of the church might be as elaborate and complicated as bishop or master builder might desire.

Constructional Gothic architecture is merely Romanesque with this rib-vaulting and the resulting lightness and freedom added; but decoratively there came into it a great enlargement and enrichment of the Romanesque sculpture. The carvers grew wonderfully more learned in their knowledge of anatomy, and of the human figure in movement and in repose, and they learned to cast drapery in the most effective way, so that the culminating sculpture of the 13th century may rank with the architectural sculpture of Greece in beauty. Representing this perfection of the style we have the Cathedrals of Reims, Bourges, Amiens, the north and south flank of Chartres (for the west end is partly of earlier, partly of later epochs) and a vast number of smaller churches and fragments of churches; thus one of the finest apses in the world is that of Le Mans. The Gothic style is

French in its origin and development, but the English took it over at a very early date and built the lovely cathedrals of Salisbury and Lincoln and the still earlier east end of Canterbury. In fact, English Gothic is of the most fascinating character, though without the vastness and dignity of the French and without its logical perfection. There is splendid Gothic architecture in Spain very closely copied from the French, and in Germany the succeeding French styles are continually reproduced with modifications — the Germans very properly clinging to their noble Romanesque and only in part accepting Gothic achievement.

The early development of Gothic architecture was checked by the civil wars in what is now France — the quarrels between great nobles and the invasion of the English kings, Edward III. and Henry IV. claiming the crown of France. In this way the century from 1345 to 1453 was a time of almost continual disorder, and but little architectural change took place during that time. What little was built in the 14th century is of extreme interest, such as the Church of Saint Ouen at Rouen in Normandy, marking the very culmination of formal and regulated Gothic. In England, too, the Gothic style worked out its own evolution with singular results. The remarkable nave of Lincoln Cathedral and that of Litchfield were built with vaulting a little artificial in that many more ribs were put in than were needed, and this led immediately to what we know as fan tracery, which marks the close of the 14th and the first half of the 15th century. The most splendid specimens of this are of the 15th century, but its earlier examples, such as the cloisters of Gloucester Cathedral, are contemporary with the English perpendicular Gothic and belong to the last few years of the 14th century. Gothic art was also introduced into Italy; but it had no complete mastery there. Its nature was hardly understood by the Italians, but beautiful and highly decorative churches and city houses resulted from their work with it.

With the close of the Hundred Years' War there appeared all over northern Europe the style which we call Florid or Flamboyant architecture, but it is to be noted that the glory of this style is almost exactly contemporary with the rise of the classical Renaissance in Italy. From 1453 till 1525 the Florid Gothic was in the main undisturbed in France, and a similar style prevailed almost undisturbed in Germany, Flanders, the Low Countries and England; but all this time the buildings of Italy were without exception built in what was intended to be the classical Roman style of architecture. This period, which should be called by the Italian name, the Risorgimento, is therefore to be studied by itself in Italy, and the style of the Risorgimento, beautiful in itself and full of interest, has this further hold on our notice that it was destined to prevail over all local styles and to turn the people of Europe toward the imitation of Greco-Roman art. The classical style of Italy has, of course, the fault of being a deliberate re-study of a style long before forgotten and abandoned — that is to say, it did not grow naturally from the study by each master builder of the buildings of his predecessors and contemporaries — it was studied deliberately because it was felt that the remains of the great civilized empire of Rome must be better than the work of the comparatively disorganized and scattered peoples of mediæval Europe. This fault disappeared, however, after the first few years of hard and persistent work, by so many artists all working together; and yet it is certain that in architecture there was less of a success achieved than in other forms of decoration, and in painting and sculpture conducted with the purpose of recording expression. What we call the Renaissance architecture of Europe was not destined to develop any new system of building nor any system of sculptured or painted decoration except as it offered room for beautiful separate works of art to be put into place on its walls and in its niches. The Italian influence reached the North early in the 16th century and by 1525 it was established in France.

The important buildings of this neo-classic style were in Italy very largely ecclesiastical. There had not been during the 13th century such a wonderful building of churches in Italy as in the North, and so when the new style came in there was room for more. Of the early date are such churches as Saint Zaccaria and Saint Fantino in Venice, the church at Montepulciano and the similar one at Cortona on the hillside, and the church of Saint Andrea at Mantua. There were also a number of city residences of the nobles, buildings which we call palazzi, and some of these, such as the Palazzo Rucellai, the Palazzo Riccardi, the Palazzo Strozzi, and the Palazzo Pitti in Florence, with some of the most exquisite private houses in the world on the canals of Venice vie with the most important churches of the period. Again in the 16th century the architecture, though less varied and natural, seeming also comparatively cold and hard, as if the delight in it had gone out of its creators, is full of excellent examples for all students. In the North great country mansions were the first to receive and show the Italian influence, and very splendid buildings of this sort were built in France during the reign of Francis I. and Henry II.; while in England during the contemporaneous reigns, the curious Tudor and the still more interesting Elizabethan style were not showing marked Italian influence and yet were evidently not simply the development from the latest English Gothic. It is curious, however, that the use of Gothic details and even of Gothic building lasted in England far into the 17th century, though it was then not very general.

By 1650 all marked separation of style between the countries of western Europe had disappeared. All the peoples were building alike in the modified Roman style, with classical columns or studies made from them, and with complete abandonment of all mediæval forms. The great influence over taste of the brilliant court of Louis XIV., the building of Marly and Versailles, had a still greater influence over the capital cities and royal palaces of Europe, for every sovereign prince (and there were hundreds of them at this period) felt himself obliged to try to build a little Versailles for himself. In this way the universality of the later neo-classic was established; and this prevailed continuously down to the outbreak of the French Revolution. It is not meant that there were no changes nor that there was a lack of intelligence and thought, for there were architects of real merit and there

were modifications of style so decided that there is no difficulty in dating a good piece of architecture; but the curious fact that this universally prevalent architecture observed two rules and not one, gave it in all its forms a marked characteristic. In every other strong and prevailing style that the world has known, tradition and the handing on of rules from master to pupil was the one cause of uniformity and the one route of change; but now for the first time there was a body of ancient learning and often of misinformation about the Greco-Roman past to which every one referred as to an authority greater than that even of his master and of his contemporaries.

Since the close of the Napoleonic wars in 1815 there has been throughout Europe and in the lands settled by Europeans an architectural situation altogether unique in history. There has been no universal and no generally prevalent style except that the later neo-classic in one form or another has been continually in use. Every other imaginable attempt has been made; and there have been earnest and resolute studies in Romanesque, Gothic, Mohammedan and even Byzantine art, and experiments have been made in Egyptian, Persian and other far removed styles. The early Renaissance, too, both that of Italy which we called above that of the Risorgimento, and the Renaissance proper of France; and the English Elizabethan and Jacobean, and the spirited and picturesque German Renaissance of the 16th century, all have been tried. Modern architects have not merely sought inspiration in the buildings and in drawings and photographs of the buildings, but they have tried to copy them either complete or in great part, large details and small, and it is largely true that the 19th century was so poor a time for decoration because all the designers had their portfolios full of examples of old work finer than anything they could produce. They were trained to copy and adapt, and in this way prevented from trying to design in a natural way. In Bavaria the traveled and studious prince who was afterward King Ludwig I. (dethroned 1848) built a whole series of palaces and official buildings in the capital city, Munich, and in its neighborhood, trying in turn to reproduce Byzantine, German Gothic, Florentine Renaissance, Greco-Roman and Greek as nearly as he dared. These buildings are permanent and solid structures, and a serious attempt was made to build up in this way a museum of architectural art, a thing absolutely inconceivable to a sovereign in the days of living architecture. There has been a German classical school, of which the chief centre was Berlin, and there have been several picturesque or semi-Gothic schools, but none of them permanently successful. During the last 20 years of the 19th century two influences were seen side by side, the one a determined effort to revive the latest neo-classic — the *Barock* of the German 18th century; and the other a very realistic study of the requirements of the building and of natural form for its ornamentation. In this last mentioned style very beautiful effects have been produced by means of stucco relief combined with the stuccoed brick front of the large city houses and public buildings, and also great boldness in the way of wrought-iron work used as an important part of the façade. In Belgium, especially in Antwerp, this use of wrought iron is very noticeable and effective. In England the Gothic revival which began as early as 1845 had largely a religious foundation, and in part a mistaken national feeling behind it; but in the main it was a protest against what was thought the artificial style derived from the teachings of Palladio and his latest imitator, Sir William Chambers, and a desire to return to a constructional art. It failed of success because at no time did it command the adhesion of more than a certain large fraction of the whole number of architects, and also because its advocates themselves did not agree as to the style which they were to develop. Great freedom was shown in adapting motives from different countries and different epochs. Thus the Italian Gothic, with a free use of color in external and internal design, was followed with great energy, sometimes in the way of close copying, sometimes in the way of bold adaptation. This resulted in admirable single buildings, but it added to the confusion of aim and purpose and prevented the building up of a consistent school of design.

This curious architecture, with pointed arches, colored material used in stripes and patterns, shafts of polished marble or granite, and architectural sculpture of very naturalistic quality, has been called the Victorian style, or Victorian Gothic. One of its earliest examples was the London church in Margaret Street, Cavendish Square. But the masterpieces of the Gothic revival are such buildings as the Cathedral of Truro in Wales, and that of Adelaide in South Australia, which are really Gothic buildings though built in a modern way to meet modern requirements. In France the tradition of the reigns before the revolution and of the brief empire of Napoleon were so strong and were represented by so many highly trained architects, sculptors, decorative painters, wood-carvers, and stone-cutters that no serious attempt was ever made to change the style of the whole country. Individual architects and archæologists preached the glory of the French mediæval tradition and occasionally a great convent would build its church in a really vigorous and well-understood Gothic manner, but in general the style of the epoch was developed according to the teachings of the central school in Paris, so that while the long rows of handsome dwelling houses and the stately Préfectures and Mairies of France were built in what might be called an orthodox French neo-classic style, the exceptional buildings are, in a curious way, harmonious with the general result. Thus the famous building on the Trocadéro Hill has largely a Byzantine character, and yet does not strike one as wholly out of keeping with the neo-classic house-fronts near. The great Hôtel de Ville of Paris, built after the destruction of the former one in 1871, is of French Renaissance, or rather of its modifications under Henry IV., but carried out consistently; and yet this building also harmonizes well with what is near. It is only now and then, in a great columned building like the theatre at Bordeaux, and the Bourse (Stock Exchange) in Paris, that there seems to be a wholly different style employed, for Gothic buildings are so very unusual in the cities that they do not count at all upon the modern aspect of the town. Much of this tendency in France is due

to the learned character of the criticism there, much less sentimental, much less swayed by general theories of what is right and wrong, far more traditional and kept in place by the social unity which marks French thought. As regards the rest of Europe, the same tendencies are visible which show even more plainly in the United States, to which we must devote the remainder of our space.

Russell Sturgis, F.A.I.A.,
Author of 'Dictionary of Architecture.'

Architecture, American.—The establishment on a firm basis of the present national government at Washington is nearly contemporaneous with the beginning of the 19th century, and before many years had elapsed the Federal buildings in Washington attracted the attention of historians. Congress met in Washington in Nov. 1800, as if with expressed determination to be in session there when the new century should begin. At that time, though the capital city had been for 10 years decided on and its exact location determined, the only buildings which the Federal government found ready for its use were a part of one wing of the Capitol and as yet incomplete buildings for the Treasury Department and War Department. The White House was not yet ready for its proposed use as a residence. Nor did these buildings make very good progress, and when they were burned by the British army in 1813 but little loss was suffered.

After the war with Great Britain, the Capitol was rebuilt rapidly, and completed in its original form, as many men now living remember it, with a low central dome over what were then the wings occupied by the Senate and the House of Representatives. The White House also was finished in its present form, though the completion of the portico lingered for a time. The «Octagon House,» now occupied by the American Institute of Architects, is reputed to have been used by the President during the building of the White House; the building is not octagonal, however, but of an ingenious and unusual plan well calculated to provide an agreeable residence.

Otherwise, throughout the United States there was but little change or development in the line of architectural art. The Georgian epoch of design had passed, except in the construction of dwelling houses. A Greek taste prevailed, and an ambition to produce Grecian architecture was uppermost in the minds of all who undertook public buildings. The lyceums or town halls throughout the country, the city halls and court houses, and State houses or capitols, were generally designed with colonnades. Of this nature is the principal building of the college designed under the auspices of Thomas Jefferson, if not by that statesman himself; of this character is the old custom house (now the Sub-Treasury) in New York, which is a very faithful copy of a hexastyle Doric temple; and of this character are the Nashville State house, the capitol at Montgomery, and a great number of buildings, large and small, in the North as well as in the South, erected at all periods up to the middle of the century. At the same time, however, the dwellings were much more commonly in the grave and decent style which we have generally called «Old Colonial architecture.» In this respect New York city was peculiarly fortunate. Whole quarters of the city were thickly built up with houses of the most satisfactory style which has yet been employed in domestic architecture in the United States — or, at least, which has received general acceptance. Many single blocks or isolated buildings throughout that part of the city which lies south of Bleecker Street still remain in their original condition, and in these is to be seen the original American domestic architecture of the time before 1835. Of the same years are many interesting houses in the New England towns, as well as in Maryland and Virginia. These houses of the 19th century are often confused with the much older houses which are properly «Colonial,» and, indeed, are distinguishable only by the student who will observe the architectural details with some care. The taste for Greek architecture is, it is true, traceable in them in the rather frequent appearance of a colonnade of four or six or, as in one well-known case in Farmington, Conn., of five columns — a nearly unique architectural device. At any time between 1820 and 1850, if a wealthy man wished to build himself a house of unusual stateliness, he would turn the simple domestic «piazza» into a portico of Græco-Roman dignity. Thus in Charleston the Ficken mansion has a hexastyle portico at least as dignified and nearly as large as that of the custom house, and a large mansion on South Battery has a Corinthian portico of four columns serving as its entrance porch. With the years beginning with 1835 the houses of the cities became more often large than handsome, with costly mahogany doors, large rooms divided by colonnades of white-painted wood, and very ample and easy staircases — all of them features known to the country mansions but hardly to city life till that time. Here again New York city is the most important centre of interest, for the houses of Washington Square and those in West 8th Street (Clinton Place), East 9th Street (Brevoort Place), and East 8th Street (St. Mark's Place) are very generally of this type, and never since that time have rows of street houses been so well handled or their interiors so well understood. The houses of Boston at this time were as good internally, and had certain peculiarities of plan recommending them to the student, such as the use of the alley passing through and under the house to the back yard, of the utility of which plan much might be said; but their exteriors were generally less noticeable. The narrow and crooked streets and something in the popular taste almost forbade external display or even elegance. In Philadelphia, on the other hand, severity was caused rather by the strong Quaker influence than by anything in the external character of the town, while the easy access to white marble in considerable quantities made this a favorite material. Hence arose the well-known type of the Philadelphia house, with walls of red brick, white marble lintels, sills, and doorsteps, and, as the houses were built close to the sidewalk, without areas and with the entrance nearly on a level with the street, a display of solid white-painted wooden shutters which carried out the chromic effect to the full.

The cities of the South were less crowded, less busy, more decidedly marked by the distinc-

tion between elegant and humble dwellings. In Mobile, Charleston, and Savannah, the characteristic dwelling was rather a more stately mansion standing free or nearly so, and having broad verandas or "galleries" which, however, were not turned toward the street, but sidewise upon gardens. Savannah, however, has a very unusual plan: a succession of square, open "places" from each of which four streets lead in four directions, giving a series of square corners and allowing of an irregularity of shape in the house-lots which is not known in our other cities. It is a matter of regret that this plan is not preserved in the newer quarters. The residences in Savannah commonly have windows along their sides opening upon a garden, which, if small, is private, made so by brick walls of sufficient height.

The Gothic revival made itself manifest in the United States at an early date. Few carefully designed buildings in the mediæval styles had been built even in England, when, in 1839, Richard Upjohn took charge of the work on Trinity Church in New York, his task there passing almost immediately into the designing of a wholly new structure, which was finished in 1846. At about the same time the Church of the Holy Trinity in Brooklyn, which still stands unaltered, was built by Lefevre, whose name is almost forgotten because of his death soon after the completion of this one important work. These buildings were carefully studied from the English Perpendicular style; and as English Gothic hardly included vaulting as a necessary feature, this was wholly omitted in the American examples, though unfortunate afterthought caused some poor imitations of vaulting in woodwork and plaster. Apart from this the churches were solidly built and with attention to the archæological propriety of every part; the inevitable slips in this direction being caused by the great lack of recorded and accessible knowledge in those pre-archæological days.

No form of Pointed style was in common use for any other buildings than churches; the same architects who did their best to build Gothic churches preferred to design private and business dwellings of different aspect, though there appeared a few buildings which, like Harvard College Library and Yale College Alumni Hall, were reminders of English collegiate Tudor architecture. Upjohn, apart from his Gothic proclivities, was rather famous for his small Italian villas, some of which were of singular grace of design; and A. J. Downing, the landscape gardener, though he occasionally put pointed arches and a steep gable roof to a cottage, carried his Gothic efforts no further than this, and seems to have preferred Elizabethan or some other semi-classic style for the numerous country houses which he designed. The public buildings of the time just preceding the middle of the century (nearly always of pseudo-Greek style, as has been said above) were unimportant, and have been, in the main, replaced by more impressive structures. The country houses were also, as a general thing, without marked character, and the rows of street fronts in New York, Philadelphia, and Boston, and in the newer and rapidly growing cities of the West, were unmarked by architectural intelligence.

In a very few cases a larger house was designed with some faithfulness, preserving a little of the simplicity of the bygone Georgian period, or carefully studied from French Parisian building, or the more tranquil and simple city fronts of Italy. Still, the arrival of the year 1850 found no important architectural movement existing in the country; nor was this year followed by any very marked development. Two or three years later J. Wrey Mould came from England and began to build the Unitarian church in New York at the corner of Fourth Avenue and Twentieth Street. His design included a lofty and slender campanile, which has never been built; and the church was marked by a character of architectural and sculptured detail and by logical solidity of structure that are even now not very familiar to American designers. This, however, was Mould's only great chance; his other buildings were comparatively unimportant, and his work in the adornment of Central Park in New York is undistinguishable from that of other artists employed upon the same terraces and bridges. St. George's Church in New York was completed, except for the spires, in 1853, under the direction of Leopold Eidlitz, who succeeded to his former partner and, perhaps, the first designer of the church. This church has since been injured by fire, and altered; but the original scheme, with an undivided and unbroken interior, and a roof supported by carefully designed timber trusses of two patterns, alternating one with another, was one of the boldest and most satisfactory buildings in the United States. The spires were built by Mr. Eidlitz a few years later, and were remarkable as the only pierced spires of Romanesque design known to students; but, unfortunately, the poor quality of the stone caused their removal. The above-mentioned buildings had architectural character, but the greater part of even the respectable and useful structures of the time were comparatively devoid of it. The Boston Athenæum, with its good plan and really excellent reading room; the New York Astor Library, the Boston Public Library on Boylston Street, finished about 1858, and some smaller buildings which the Eastern cities managed to pay for during the decade from 1845 to 1855, were generally as devoid of individuality as were the stone-faced hotels and State houses of the time. During the years from 1845 to 1860 the building of the Southern cities and their immediate neighborhood was carried on much in their old lines — the lines of the Georgian architecture. What deviation there was from this was still rather in the direction of the supplying of obvious needs. Thus, the houses of Beaufort and of other seaside summer resorts were not unlike English Georgian manor houses, with this peculiarity, that they were large with a few spacious, open rooms and wide halls, giving the idea of small and simple English manor houses increased in scale — a scheme very appropriate to the low latitude and the steadily warm summer weather. New Orleans, most conservative of American cities, showed no change in its outward aspect. The Western cities had received the inoculation of the very evil system of irrational ornamentation which marked also the buildings of the East, as will be stated farther on.

About 1855, Richard Morris Hunt, having returned from Paris, where he had been a student and also assistant to a prominent Paris architect, built the Studio building in West 10th Street, and the since-destroyed private house on the north side of West 38th Street, putting into these something of that French completeness of plan and of exterior disposition of parts which the country had hardly known before. Hunt also established an atelier on the Paris plan; and half a dozen of the architects most successful and most reputed between 1870 and the close of the century were for a time inmates of that studio. Experiments were tried in those days — experiments both in material and design — which it is sad to see were wholly abandoned during the years which followed. Thus, when Upjohn built Trinity Building in New York, a business building, a mere investment for Trinity parish, he used terra-cotta for the cornice, and by this means obtained a boldness of overhang which he would hardly have dared to give in stone. Terra-cotta had to be imported in those days, or, if not imported, then made by means of a special plant and fired in furnaces erected for the occasion. It is easy to see why the experiment had no immediate results. So in design the churches on Fifth Avenue — that of the Ascension, at the corner of 10th Street, and the Presbyterian church 300 feet farther north, together with the church at University Place and 10th Street — were all of about this period, and in them was more intelligent designing than generally in the civic buildings of the time; but there was room for more originality in the latter, and the buildings by Hunt above named and a bank in Wall Street by Detlef Lienau held out more promise. Other business buildings of great importance date from this time; two of them were built by Eidlitz in the business section of New York, both of singular solidity and of thoughtful design, which cannot now be judged, as one has disappeared and the other has been altered out of recognition.

The war came, and while some important enterprises took form during those four years of excitement and rapid thought, but little of importance was brought to perfection. The conditions were peculiar; many of the architects and many of their possible employers were in the army; but those who were at home, although often for a short visit only, were full of ambition. So it happened that both industrially and artistically the years immediately following the war were very active. In the Eastern cities, the domain of business began to encroach rapidly upon that which had been the residence portion, and whole streets were built up with buildings of somewhat pretentious character as to their outsides, the masons and stone-cutters making fortunes out of the simpler work upon so many precisely similar fronts; the residence streets were lined with buildings of constantly increasing cost, and also the construction of country houses became an important employment for the builders in the smaller towns. A few years were still to elapse before the more important public and private buildings took shape; this was the epoch of much building of less pretension.

The result of the mingling of styles and the clashing of different tastes and fancies was very curious. Philadelphia buildings kept nearer to their old type of red brick and white marble and simple design; Boston buildings were far more often designed by architects employed, each one for a separate building by the owner of the soil. New York, following its unfortunately deeply-rooted habit, built itself up in long rows of stores and houses, each for sale to any possible buyer, and therefore of necessity deprived of individual character. And yet the difference in architectural merit of the buildings in the three cities was not so great as might be assumed. The critical students of 1865 abhorred the New York brownstone front, with its high stoop and its exaggerated affectation of Corinthian elegance, and they envied Boston her intelligent Harvard graduates who owned lots and would build houses for themselves, and who employed other Harvard graduates to design those houses. But Philadelphia and New York, sticking to their traditions, produced at least less that was monstrous and impossible than Boston. There was more intelligence in the Boston buildings, but there was also more whim. The dreadful heresy of eclecticism got hold of a few of the Boston men, and the Gothic buttress topped by an Ionic pilaster, a motive which passed into a proverb, was only an extreme case of what was a serious injury to architectural growth. The Gothic revival in the hands of Peter B. Wright, J. Cleveland Cady, Calvert Vaux, Frederick Clarke Withers, and John Sturgis, led to the erection of some important buildings; the Boston Museum of Fine Arts, fronting on Copley Square, being the most florid of these, and embodying the English terra-cotta building of the day. The Academy of Design in New York was the only building ever erected in America in which a serious effort was made to design an abundant sculpturesque decoration on the principles of the more advanced preachers of the gospel of mediævalism. The labor and thought required for such work prevented any immediate following of this example, and it soon appeared that the taste for Gothic buildings was not deeply rooted among the architectural students of the time. Good buildings were designed by the men who have been named, and Richard Upjohn's admirable Trinity Chapel should be added to the list of Gothic churches deserving special praise; but the general effect of the taste for pointed windows and for the ornamentation supposed to belong to them was very unfortunate. It had much to do with what was certainly the most unsatisfactory epoch in American architectural designing. The years from 1865 to 1875 saw the erection by the hundred of the most insufferable country houses that could be imagined. All architectural sense seemed to have gone out of the designers. The posts of the verandas were cut into shapes suggested by nothing in the world except children's toys; window-heads of hitherto unknown form were put into woodwork, into cast-iron, and even into stone; a variety of roof known throughout the country as the French roof, and consisting of a lower slope so steep as to be almost a vertical wall, and an upper slope so flat as to be a mere "deck," produced the ugliest skylines conceivable. The country was full of carpenters and masons who thought themselves architects because they had purchased and studied some book containing plans and elevations of famous buildings. These men were trying

"FLATIRON" BUILDING, NEW YORK, IN COURSE OF CONSTRUCTION.

"FLATIRON" BUILDING, NEW YORK.

for originality; but this search, difficult and dangerous even among men who have had previous training in artistic designing, becomes ruinous when followed by the men of an epoch and a country as devoid of artistic sense as those which we are now considering. Buildings were planned without any artistic perception of the necessities of the plan; a room was thrust out to the east and another to the south and another to the west, these different wings having no relation to one another or to the central mass, which, indeed, they might entirely conceal or even destroy.

The same incongruity of design affected even the public buildings of the time. These were the days of Harvard Memorial Hall, of the first and accepted design for the capitol at Albany, of the United States government buildings, including the post-office and court rooms in the same huge mass, which were erected in many of the cities of the land, and of very numerous buildings which the designers, if now living, would with perfect propriety disclaim, classing them as the work of their salad days. Men who have since proved themselves capable of much better things produced the most unfortunate designs during those hurried years. The *Tribune* building in New York, the Boston city hall and court house, the earlier public buildings of Chicago, the Connecticut State house or capitol at Hartford, may all be named with those cited above as specimens of what ought not to be done in architecture, and yet as the buildings of men who have since proved themselves capable and dexterous. It is, indeed, true that a flood of bad taste covered the land, and that few detached monuments of some little architectural merit could be seen above it.

A more promising condition of things was seen to exist when the third quarter of the century was completed. In 1875 the older men who were still busy had learned a great deal by experience and by their own blunders; the younger men began to come in, more or less well taught in Paris — at all events certain of the fact that there was such a thing as 19th-century architecture and that as yet the United States had hardly achieved it. Henry Richardson was busy as early as 1875, and a very few years later he took up definitely that Romanesque style which he had studied in central France — took it up, and built thereafter according to its doctrine, without forsaking it for a moment. Trinity Church in Boston, partly studied from Spanish models, was one of his Romanesque buildings — perhaps the earliest of them. Nearly contemporaneous with this were three important churches in Boston, one of them by Richardson himself, the others by the younger Upjohn and Cummings and Sears; and several large churches of considerable merit were built in different mediæval styles in New York. The older Upjohn, the designer of Trinity Church 35 years before, made of St. Thomas's Church, when rebuilt on Fifth Avenue, his crowning labor. The present writer built many college buildings between 1870 and 1880, and, in connection with George Fletcher Babb, built Battell Chapel of Yale College and a bank building in Albany, each of these in a modified Gothic style. Other college buildings, by George B. Post for Princeton College, by H. H. Richardson for Harvard University, and by J. Cleveland Cady in several parts of the country, assisted greatly the advance of style; and Trinity College, near Hartford, was begun on a great scale and in a consistent English Gothic style from the designs of William Burges of London. The admirable buildings of Columbia College at 49th Street, New York, were built by C. C. Haight at a later time, and the same architect built theological seminaries and hospitals in and near New York, all in some form of English Collegiate Gothic. Of younger men, the firm of McKim, Mead & White, who had built the large and interesting buildings known as the Tiffany house and the Villard-Reid house in New York, designed also the Newport Casino, and in doing this helped much toward a development of country house architecture which, indeed, has constituted the most important artistic result of the quarter century. The American frame house, sheathed with clapboards or shingles, is, in the hands of architects of taste, the best thing we have yet to show. A few years later the firm of Carrère & Hastings designed the spirited Spanish-looking palaces used as hotels in St. Augustine. All these buildings had character; but there were still traces enough of the old unarchitectural designing, and this especially in the more important buildings, as is natural. The original designs for the Albany capitol and for the Philadelphia public buildings were nearly as devoid of architectural merit as if they had been built 40 years earlier.

Since 1885 there have been many more buildings of cost and of great pretension — many more buildings which in scale reached the standard set by the continental nations of Europe — than at any previous time. Club houses of great importance, dwellings of such cost and dignity that they are really and in every sense of the word palaces, and national and municipal buildings, into the design of which some architectural ambition has found its way, are now so common that even a bare list of them would fill more space than can here be given. If the progress of architecture since that time has not been all that could be hoped, this fact is to be ascribed to the rapid increase of new demands upon the architect's attention. New problems have developed themselves much more rapidly than the comparatively small number of intelligent architects could work them out. The common use of the elevator made 10-story buildings as easy to administer as the four-story buildings of old time, and the hotels and business buildings were at once changed in this radical way; whereupon it was found that the design which had served for a four-story building was not capable of ready adaptation to the new conditions.

Hardly had this been realized and the problem fairly got in hand when the introduction of the steel-cage form of construction revolutionized anew half the building of the American world, and the 10-story front had to be reconsidered for 16, 18, or 20 stories. Moreover, while the 10-story building, like its predecessors, had been a structure of solid walls, carrying iron-framed floors, the steel-cage building was felt to be a totally different construction. Here was a skeleton of uprights and horizontals, and no thoughtful architect could jacket such a structure with a thin stone-faced or brick-and-stone-faced wall without feeling that this was a mere simulacrum of building and that the real secret

of the new design had not yet been discovered. So, too, with the churches, although they were not required to be of unusual height, and although the steel-frame structure hardly suggested itself as fit for them, their condition was felt to be changed by the monstrous height of their neighbors, the insurance buildings, the hotels, the apartment houses. A church with a 200-foot steeple and a 70-foot high roof-ridge made but a poor show alongside of a tower-like mass as large horizontally at top as at bottom, and carrying a level cornice higher than the steeple-cross of the church. Moreover the architects whose work was of such quality as to please greatly the more instructed part of the community — a community full of a kind of literary intelligence, but without much training in the arts which address themselves to the eye — those architects found themselves overwhelmed with work. It is not in human nature to refuse a $20,000 or $40,000 commission; it is not in human nature to confess the impossibility of doing so much work and doing it well. The result is a general tendency toward a method of design which, in the best instances, is markedly controlled by good taste, by the abstention from incongruities and ill-considered details, but which may be almost devoid of the evidences of thought. The colonnade taken bodily from an ancient building, or a theoretical plate in an old book, the evenly spaced windows capped by a little delicate sculpture, the roof either invisible or of low pitch and masked by a balustrade copied from an Italian palazzo — these and other such architectural members are united without shock and without repulsive incongruity in buildings which do their appointed work quite well — which accommodate a family or a congregation, or which prove to be paying investments — and the community is fairly well satisfied. The extreme rarity of anything novel in design goes with this abrupt explanation of our present state as an architectural community. Louis Sullivan of Chicago is left alone in his serious and repeated efforts to design the exteriors of lofty steel-framed buildings according to their nature and the requirement of the law and modern custom. A. Page Brown, recently dead, was alone in having a separate and little-known national style in which to build his California College buildings. Heins and La Farge are almost alone in having a large church (the Cathedral of St. John the Divine) put into their hands to be slowly elaborated and perfected in design, even as the preparatory work progresses. Shepley, Rutan, and Coolidge of Boston are almost alone in having a chance to build a costly and massive structure (the west portal of Trinity Church), with an abundance of representative and ideal figure sculpture forming an essential part of the architectural design. Wilson Eyre has few to help him in his gallant effort to create a truly decorative system of sculpture for buildings which can have but little of it. Sculpture is, indeed, added to a few of our buildings of neoclassic design, just as mural painting is used within, but this without modifying the architectural character of the structure.

The conclusion seems to be that while the artistic mind of the country has well outgrown the period of callow haste and of ill-bred ugliness, it has hardly as yet entered upon a true architectural progress. The possibilities of such progress are evident; moreover, there are artists enough who feel the need of it; but whether the mind of the community, giving its best energies to money-making, will in the course of the next century apply itself with serious purpose to architectural art is, perhaps, as uncertain now as it was in 1850.

RUSSELL STURGIS, F.A.I.A.,
Author of 'Dictionary of Architecture.'

Architecture of Transition, that which shows somewhat rapid change from one important style to another. Strictly speaking, the architecture of all periods before the wars of the French Revolution was continually in a state of transition, though since that time it has been influenced rather by sudden attempts at reviving styles long since forgotten. A natural transition was always going on; but there were epochs when the changes in progress were of a specially radical character. Such a time was that when the more stately architecture of the city of Rome and those towns and lands which depended upon it, was undergoing a change from the columnar character given it by the Greeks, to the vaulted and arcuated character resulting from the introduction of Eastern methods into Italy. This subject is treated in the general article ARCHITECTURE, and under ROMAN EMPIRE, ART OF; but it may be pointed out that the exact time of the transition cannot be fixed. The famous Pantheon in Rome, a round building of immense solidity roofed by a cupola, hemispherical as seen from within, but low as seen from without, was long supposed the earliest specimen of solid masonry building. The walls and the dome alike were built of rubblestone laid in strong cement mortar, but without much reference to the curvature of the vault or the preparation for the different openings — doors, windows, archways. These were built up and the building outlined in the first place, by means of brickwork of very hard and perfect material and workmanship; then the great weight of the wall and vault was added, and the resulting building, with rough surfaces of stone and mortar without comely or orderly arrangement, was faced up, finally, with stucco or with slabs of marble within and without, and according to the place of each member in the completed building. The Greek columnar system, and especially the Corinthian order, was used as pure ornament, and for the interior alone; the marble columns carried no weight except that of the slight entablature put in place merely to complete the order and to give a finished architectural look to the whole. This building was long supposed to be the historically celebrated Pantheon of Agrippa, and to have been built during the principality of Augustus about 25 B.C. It is now known that only the portico can be of that time and that the round building dates from the reign of Hadrian and is of about 120 A.D. We have no knowledge as to the chronological order of other early buildings of the same character. The thermæ at Caracalla were built about 215 A.D., the thermæ of Diocletian about 290 A.D., the basilica of Maxentius and Constantine about 310–20 A.D.; and all these buildings have their great halls vaulted with groined vaulting as massive as the cupola of the Pantheon and built of masonry in a similar fashion. No one can fix the beginning of this system, nor is it possible to say what buildings in the Oriental

provinces of the empire gave rise to the new structure. Etruscan example can hardly be thought very influential in this. It has been suggested that the lost architecture, at Alexandria and other great towns of the East of the time of the successors of Alexander the Great, would, if it could be explored, reveal this secret. All that we can say is that the chief buildings of the empire from about 100 A.D. until the fall of the western empire in 475 A.D. were vaulted structures adorned by pseudo-Greek columns and pilasters, grouped in screens or used in couples or singly as apparent support for the vaulted structure, and the surfaces of masonry adorned with marble or with stucco in figured bas-relief, and with painting and gilding.

It is possible, however, to mark out the close of this period of transition. The palace of Diocletian at Salona, where now is the town of Spalato, was built after 305 A.D., and that building is Romanesque in its character. This means that here are seen arches springing from the capitals of columns, exactly as they were to be built during the next 1,200 years, without the necessary interposition of the classical entablature. It means also that the classical ordonnance and proportions, inherited from the Greek artists 600 years before, had finally lost their hold. Buildings of the same epoch and others a little later in Syria, are of even less classical character, and even more decidedly Romanesque (see CHRISTIAN ARCHITECTURE). The recently explored ruins in North Africa are frequently of the same style of design, with completely Romanesque treatment of arch and abutment. This character is seen, too, in buildings as early as the Arch of Hadrian at Athens, and the arches at the two ends of the famous bridge at Saint Chamas in southern France. In each of these the great arch springing from the abutment on either side is not in any way subordinated to a pair of columns or a pair of pilasters; columns are used, indeed, but only to adorn the outer edge of the piece of walling, in much the same way as the angle shaft of the 12th and 13th centuries was to be used. Now, this early Romanesque of the 4th and 5th centuries is the organized style to which the great thermæ and basilicas named above are the transition. The building first named above, the Pantheon, may be taken as a type of this transitional architecture.

An interesting art of transition is that which marks the growth of the Gothic style out of the Romanesque. The date of this may be set at 1150–70 A.D. and the place as northern France — the country around Paris. In some of the provinces buildings even later than 1170 appear as transitional, for it took a quarter of a century before the people of the Rhine, of northern Spain, or, indeed, of the far south of France, had fully absorbed the new ideas of building. The famous Church of S. Remi at Reims may be looked upon as a type of this transitional architecture, and large parts of the still better known Church of S. Denis near Paris are of this character. These are the buildings in which the ribbed vault has been adopted once for all, and the pointed arch with it, as an almost necessary part of the actual structure, but where the round arch is still used for many of the openings in the walls and where the flying buttress is as yet far from complete.

The most important style of all those which may be called Transitional is that of the close of the Gothic epoch. The Hundred Years War in France and Flanders came to an end about 1435. There had been but little important work done on the continent during the 14th century, but in England the very curious Perpendicular style was developed, one in which the mullions of the windows were carried through until they nearly met the intrados of the arch above, so that the windows seemed divided up into series of vertical panels almost unbroken from top to bottom. The churches in this style are known by their very low roofs, nearly flat, so that they do not show above whatever little parapets may be erected upon the wall. The towers are square and generally flat-topped, with very seldom any spire or lantern and with pinnacles at the four corners. This style was continued into the period of which we now have to treat; and the transitional art in England, reaching even to the accession of Elizabeth (1558), is Perpendicular in its general character. Very different was the Florid Gothic of northern France. The Church of Notre Dame de l'Épine near Châlons-sur-Marne, and that of S. Jacques des Vignes et Soissons (ruined) are of this style, but are not its best specimens. For the full beauty of the style which we call Flamboyant, we must go to the Cathedral of Evreux and that of Narbonne. The beautiful tower of Saint-Pol-de-Leon, the great churches of S. Wulfram at Abbeville and S. Maclou at Rouen, the still more characteristic church at Saint Riquier, the west front of the Cathedral of Tours — all these are the faultless buildings of the Flamboyant style. They date from the years between 1450 and 1500; but the style continues into the 16th century. Parts of the Church of S. Maclou, named above, are as late as 1535, and that is about the date of the Palais de Justice, in the same town. The south transept of Beauvais Cathedral may be even later than this, and the famous Church of Brou near Macon in Burgundy of the years 1510–36. The reader must constantly recall the fact that during these years the classical revival in Italy was at its very height (see ARCHITECTURE and RENAISSANCE). The strange thing is the complete rejection or ignoring of the classical feeling by the northerner, the complete adoption of it south of the Alps.

The Flamboyant Gothic is not as strictly logical as the true Gothic of the 13th century, though the interior of a great church like one of those named above is apt to be as straightforwardly built and as sincerely designed as at any epoch. The change is most marked in a certain fantastical character given to the unconstructional part, the window tracery, the parapet, and the sculpture; but in England the extraordinary fan-vaulting, first seen in the cloisters of Gloucester Cathedral, but carried on in the Divinity School at Oxford (1450) and in the Beauchamp Chapel, Warwick (1460), reached its culmination in the three famous buildings which we always think of when fan-vaulting is named. These are the Chapel of S. George at Windsor Castle, the Chapel of Henry VII. at Westminster Abbey, and, the most perfect of all, the magnificent Chapel of King's College at Cambridge, finished about 1510 and embodying in itself nearly all that the Florid

architecture of England has to show. The interior is one unbroken hall lighted by huge windows on both sides, and by still larger windows at the two ends. It is 78 feet high inside, a considerable height for an English church; about 45 feet wide and about 315 feet in length; so that it has the characteristics of the best English interiors — great length as compared with height and width. The proportions are of extraordinary beauty, and there is in no place outside of France a more splendid ecclesiastical interior.

This fine Late Gothic of England passed into the architecture which we call Tudor, from the Tudor sovereigns, Henry VII. and his successors. Of this the most interesting development is that which we call the Elizabethan style, best known in the splendid country houses which were built during Elizabeth's reign in different parts of England. The architecture of some great college buildings in Oxford and in Cambridge is also of this character,— with low (four-centred), pointed arches, and generally with low-pitched roofs; but these roofs are often splendidly designed within, with elaborate timber-work forming a design even more varied and rich than the vaulting of the continent. Classical details, columned porches, and the like, were introduced from Italy, and many of the otherwise picturesque and semi-Gothic houses of the period have these curious "Italianate" features. This architecture continued into the reign of James I. and disappeared in the political confusion of the time, to be succeeded by a classical style brought fresh from Italy when the conditions which ensued allowed of costly building once again.

The Florid Gothic of France and the neighboring countries of the continent is accepted by the French writers as a part of the northern Renaissance; but we have to separate it very carefully from the Risorgimento or classical revival beginning in Italy about 1420. The reign of Louis XII. in France (1498–1515) is the time when we see, struggling with one another in the North, the classical influence from Italy, then nearly a century old in the land of its origin, and the Florid Gothic of France. Thus, at the famous Château of Blois, the wing named after Louis XII. is literally half way between Gothic and classical. Arches are three-centred and therefore without points; pillars are either round or square in section, with paneled sides, or, as at the great driveway of entrance, are combinations of square and round forms; and all these pillars have fully organized capitals of semi-classical character; but the roof is steep and is adorned with high chimneys and very elaborate dormer windows, and the design is picturesque rather than symmetrical. A square tower stands at either end of this building, of Louis XII., and each of these towers remains rather Gothic than classical to the hasty observer, although the avoidance of the chief forms of Gothic art is very marked. Almost adjoining this stretch of building is the front named after Francis I. and built only 25 years later than the building described above. This is not Gothic at all. The windows are all square and the walls have pilasters in regular ordonnance, while yet the lofty roof, the picturesque dormers, and the high chimneys remain to express the transitional character of the whole. The Church of Brou, already mentioned, is exceptionally late for a building which is entirely Gothic in style, without classical motives of any sort.

Russell Sturgis.

Architecture, Education in. *Training.*— The ideal architect is an artist who employs structure as his medium of expression,— whose function it is to produce beautiful buildings.

That this ideal is realized by relatively few of those who are called architects in our day is due to the fact that its embodiment under modern conditions involves the correlation of activities of very diverse nature; and few there are who display in just proportion the capacities these diverse activities involve. These may be placed in three great groups, and the architect's training may be correspondingly considered under three headings, namely, his artistic education, his technical education, his business education.

The student who hopes to be an artist-architect must train himself somewhat as do all artists in all other fields. Yet he cannot with his own hands bring into existence the building his imagination pictures; he is compelled as no other artist is, to rely upon the work of others in the realization of his artistic creations. Hence it becomes very important for him to gain a very special technical training in order (1) that he may learn how to indicate to his artisan helpers the nature of the work to be done, and (2) that he may become acquainted with the methods proper to these artisans in the accomplishment of their several tasks.

But beyond this the architect who would reach the highest goal should prepare himself for a business career. For unlike other artists he is usually unable to express himself in his chosen medium unless others entrust to him the expenditure of large sums of money. And if he is to be thus trusted he must exhibit executive ability, a knowledge of men and capacity to manage them, and at the same time he must possess unquestioned reliability and business sagacity.

In this connection it may perhaps be well to note that in our time there are not a few men who are counted as successful architects who are really merely good business men working in a special field, men without high artistic ideals or susceptibilities, and who gain such success as they attain by the mere direction of hired designers, and by the careful management of the business of their clients. The education of such men involves only such general training as is required by other business men, with the addition of such studies as will give them a knowledge of the architectural forms current in our time, and such a superficial acquaintance with the principles of architectural design as will enable them to choose as employees designers whose work will satisfy the average taste of their clients.

We need not concern ourselves, however, with business men of this type, for they will not be looked upon as architects by those to follow us unless they combine with their business skill the other qualities demanded of the ideal architect, to the consideration of whose training we may now turn our attention.

Apprentice System.—As is indicated by the etymology of his name, the architect was originally a master workman; one who had arisen from the ranks because he had evinced skill and imagination in guiding the construction of buildings after the methods current in his time, and who through the exercise of this skill and imagination had produced buildings which were looked upon as beautiful by his fellows.

The methods employed by the architects of antiquity are little known to us, yet as the work under their control became more complicated they must have found it necessary to employ assistants who at first were without doubt merely trade apprentices, and from among these the architects of the next generation would most naturally be chosen.

In modern times, as the use of complicated drawings has become more and more important, the architect has found it necessary to use his assistants on special work which does not involve the skill acquired by artisans in construction; and thus the type of man serving as the architect's apprentice has changed. While not an artisan himself he has learned his master's methods, and presently we find men thus trained assuming the function of the architect without any preliminary practice as constructors.

The apprentice system of education for the architect as thus developed was not unlike that adopted in the earlier days in the training of artists in other fields, and with such modifications as are natural in relation to the complexity of modern life it has persisted even to our day in many lands. In England a large proportion of the eminent architects of the day have been educated in this manner, and until within a generation in this country no other system of training for the architect was available.

A similar apprentice system obtained in the training of lawyers and doctors until a late period when special schools of law and medicine became established. The success of these schools called attention to the fact that, from a certain point of view, the architect is as clearly a professional man as the doctor or lawyer, and that the weaknesses in the training of doctors and lawyers under the apprentice system, which had led to the establishment of their special schools, existed also in connection with the study of architecture.

These weaknesses need but to be stated to be apparent to all. Evidently the teaching a busy architect can give to his pupil must vary greatly in quality and amount as the demands of his practice vary. Evidently his teaching is likely to be unsystematic; and it is certain to be biased by his individual taste, a matter which is of importance in relation to certain subjects, to be referred to below, where the broadest catholicity is of importance.

Thus following the example set in other professions, there have been established schools of architecture in which an effort is made to give the student a systematic training which shall not vary in quality and amount from year to year, and which shall avoid the unfortunate influences which are liable to obtain under the apprentice system. It will be generally conceded that the schools as a rule have been reasonably successful in this effort, if general results are considered, if particular instances are not over emphasized.

But the abandonment of the apprentice system of training in the law and medicine carried with it a loss which was generally overlooked. The newer method tended to minimize if not to eliminate the inspiration which comes to the student as the result of contact with the living master in the active practice of his profession. Nowadays students in law and medicine appreciate this loss and are supplementing their school training with practice under the guidance of men of reputation in their special fields.

But the loss to the student of architecture who fails to come under the influence of a practising master can scarcely be overstated. For the artist such an influence is of vital importance; under it he will absorb, as it were, stores of lore peculiar to his art which can never be expressed in the alien words of the lecturer, or upon the pages of a text-book. Fortunately the architects themselves are beginning to see that in one way or another the architectural student must be brought to feel this influence. What was valuable in the apprentice method of education, and has been in many cases lost, must be regained. In no inconsiderable measure it has been regained in the atelier system as developed in the Ecole des Beaux Arts in Paris, and fortunately a distinct movement in the same direction is noted in the later developments of the schools existing in this country.

Granting then that there is a vital something of supreme importance to the architectural student which the school training cannot give, let us ask what he can gain in the schools, with economy of his time and labor, in connection with the training which we have seen to be desirable in the three directions above spoken of, which for convenience we shall treat in reverse order.

Business Training.—The architect's business training cannot be materially advanced in the architectural school. The general education, and the influences which produce the reliable, accurate, and farseeing business man, can best be gained quite apart from the school course, in the practising architect's studio. In this connection it may be noted that, while the artistic side of the architect's life must always be first considered, it is easy to underestimate the importance of his business career. The student fresh from the schools too often thinks that he may at once undertake important commissions without the business experience which a long established practice brings. He will tell you that this can be purchased ready made by the employment of others to attend to this drudgery so repugnant to a man of artistic temperament.

But in this view there lurks a hidden danger to the art of architecture itself. As has been said above, the confidence of the client must be obtained by the man who is to spend the client's money, and if the skilled designer is not one who inspires this confidence the control of great constructions will surely go to men of less artistic ability, and the skilled designer will find himself directed, rather than the director of the work necessary to the embodiment in solid form of the ideas which his imagination creates. Nothing can be more dangerous to pro-

gress in architecture as an art than the establishment of a belief that the architect's function ends with the creation of designs on paper; his art product is in the constructed building, and if effective artistic result is to be gained he should actually direct the construction in all particulars and to the very end, and should train himself to assume all the labor and responsibilities this direction involves.

Technical Training.—We may now turn to the consideration of the architect's technical training, which in the first place must result in the mastery of methods of representing his conceptions so that they may be understood by his clients, and comprehended by the workmen who are to be employed to embody them in material form. This means in the main the attainment of skill in technical draughting; and this can very clearly be better and more quickly gained by the concentrated effort possible in a school than in the course of the routine work in an architect's office. The student should be warned, however, that a danger is connected with the attainment of this skill if he comes to look upon his drawings, which are no more than tools of his trade, as works of art in themselves; for these drawings are necessarily on plane surfaces, and if he gives too much thought to their perfection he is liable to overlook the importance for him as an architect of thinking in solid dimensions.

The general principles governing the representation of details of, and the writing of specifications descriptive of, the work to be done can also be learned in the schools, but little more than these general principles; the student must not hope to gain facility in these important matters without the experience of actual office practice.

Artistic Training.— It is true of all artists, as it is of poets in particular, that they are born and not made; and surely unless all opportunity is lacking the born architect of genius will show his power whatever his training may be. Nevertheless there are certain matters which even the genius must learn by his own often bitter experience, or else from those who have practised his art before him; and these matters may in some particulars be learned most quickly and surely in a school. It will be agreed for instance that each artist should understand well the nature of the medium in which he is to express his measure of genius. The medium of the artist-architect is construction in masonry, in iron, and in wood; and a thorough knowledge of the principles of construction is most important to his progress. This knowledge is the ground work of engineering, and clearly can best be gained in a school. In relation to this special study it may be said, on the one hand, that the most thorough training in engineering cannot injure an architect provided it does not take from the time to be given to other equally important matters to be referred to below. On the other hand it must not be forgotten that the architect's function is not merely building as such, but building in a manner that shall stimulate in his fellows the sense of beauty. This molding of constructional forms into shapes which are beautiful is a matter of difficulty which has been attained by architects in the past only through numberless trials, with their failures and successes; through the elimination of the ugly, and the repetition with ever increasing improvement of that which has shown itself to be pleasing. The architect has thus always worked with, and upon, established modes of construction, and he always will; and this distinguishes his work from that of the engineer, whose function it is to devise special modes of structure to meet special structural demands. It is apparent then that the training of the architect in relation to his structural medium differs from that to be given to the engineer, in that the architect does not need to gain more than a thorough understanding of the principles of structure which he is to use in his work, and this does not necessarily involve so prolonged or detailed a study of the sciences as is needful for the engineer.

The Architect as a Designer.— We may now turn to the consideration of what is of the highest importance to the architect, namely, his training as a designer. As we have suggested above, no amount of training can give to a man that measure of genius which constitutes him an artist. None the less the greatest genius will gain much if he learn the lessons taught by the experience of the masters of the past, and the man who is less than a genius were stupid if he did not welcome this teaching. The masters of architecture of the past have left us a record of the forms and relations of parts which after long series of studies and experiments they have found to be most beautiful. This record is not found in written word, but in the great monuments which have been left to us; and the study of these monuments after a certain method constitutes the history of architecture. The student should gain as thorough a knowledge as possible of this history, with especial reference to the vital development of the various greater and lesser styles, giving particular attention to those forms in which the highest perfection has been attained in the past, and making a special study of those forms which appeal to him as most likely to be of service to him under the conditions which surround him. He should also gain a considerable acquaintance with the other arts, especially with those most closely related with architecture, namely, sculpture and painting.

Evidently a large part of the information just referred to can be gained through text-books and illustrated lectures given in the schools. But as clearly is it important for the architect to study the art products themselves, and this can only be done satisfactorily by travel in the Old World, where the great architectural monuments of the past exist. Where such travel is impossible, he may gain something approximating to it by studying such models of masterpieces of the past as are available in museums, and by the thoughtful use of photographs of existing masterpieces.

In all this, however, the student will have been merely sharpening his tools for his life work; all this is but preliminary to practice in design. Here he cannot properly content himself with mere study of the works of other masters. For the conditions under which each generation works are always in some respects new, and architecture as exemplified in his work can only be a living art if the architect, while taking advantage of the artistic experi-

ence of those who have preceded him, builds to meet the new conditions in which he finds himself placed.

In these studies in design he will necessarily employ drawings very largely, but he should never allow himself to forget that these drawings are merely symbols of the art product he aims to produce; he should use every effort to avoid thinking of his design on paper as the end of his endeavor; he should strenuously train himself while he works on a plane surface to translate into the actual material substance of the building he is projecting; that is, to design and think in the solid. To this end the student should give considerable attention to modeling in clay, and he will find it most valuable to cultivate the habit of rapid and accurate sketching in perspective, and to acquire deftness in making simple small scale clay models of his *projets.*

It is in connection with this study of design that the architectural student will find it to his greatest advantage to work under the inspiring influence of a practising architect whom he recognizes as a master of his art; and it is most encouraging to note, as has been remarked above, that those who guide the best of our modern architectural schools are recognizing this fact, and are aiming in one way or another to regain the benefit to the student in this regard which was connected with the old apprentice system so carelessly laid aside in most of the schools as first established.

It must be apparent to the reader of what has preceded this that no student should undertake the practice of architecture without facing the fact that he has before him a long road, and a life of arduous effort. In the view of the writer no young man should undertake this work unless he feels within him a very powerful inclination to it. The modern world is all too full of those who choose the architect's life because they think it relatively easy and especially delightful. The latter it surely is; but the former it as surely never is.

Conclusions.— The conclusions reached may now be summarized in a few words. Beyond such general culture as he may be able to gain, the most desirable special training for an architectural student will be given by certain studies which can best be taken in established architectural schools, supplemented by careful observations of monuments of architecture in the course of travel in Europe, and by work in the studio and business office of a skilled practitioner who is a masterful artist.

It were well if life were so ordered that the acquisition of technical facility, and the study of design under a master, could begin in early youth, and continuing could fill the leisure hours of the student while gathering the store of general information which tends to broaden his life; but under existing conditions such an order of work is difficult to arrange.

If choice is to be made among the architectural schools, the one chosen should if possible be one situated in a city where building operations are proceeding on a large scale, and especially one in which design is taught by masters of architecture who are in active practice.

Finally the student would do well who could manage to obtain a position in the draughting room and business office of some architect in active practice during a large proportion of the long school vacations so generally given during the summer season. See PAINTING, EDUCATION IN; SCULPTURE, EDUCATION IN.

HENRY RUTGERS MARSHALL.

Architrave, är'kĭ-trāv, in classical architecture and imitations of it, the part of an entablature which rests immediately on the heads of the columns, being the lowest of its three principal divisions; also the molded enrichment on the faces of the jambs and lintels of a doorway or window, this being a part of the entablature carried around the opening and mitred at the upper corners.

Archives, är'kīvz (Latin *archivum*), a room or building in which are kept the records, charters, and other papers belonging to any State, community, or family. Very frequently the name is applied to the documents themselves. The archives of the United States are now superintended by the heads of departments.

Archivolt, är'kĭ-vōlt, in architecture, the ornamental band, often of moldings, on the face of an arch and following its contour.

Arch of Con'stantine. See ARCH, MEMORIAL.

Arch of Septi'mius Seve'rus. See ARCH, MEMORIAL.

Arch of Ti'tus. See ARCH, MEMORIAL.

Arch of Tra'jan. See ARCH, MEMORIAL.

Archons, är'kŏnz, the highest magistrates in Athens. There was for a long period only one archon, who possessed for life all the power and dignity of a king, and was chosen from the royal race of Codrus. In 752 B.C. a change was introduced, and the tenure of the archonship was restricted to 10 years, the person appointed being still a member of the royal race. In 714 the latter condition was abolished, and the archonship thrown open to all the Eupatrids or nobles; and in 683 a still greater change was introduced, the office being now made annual, and its functions distributed among a body of nine. The reforms of Solon threw the archonship open to all who possessed a certain amount of property, whether noble by birth or not; and in 477 Aristides made it accessible to all Athenian citizens, without distinction. Until 508 the mode of election was by suffrage of the nobles; election by lot was then introduced, and the person elected had to undergo a scrutiny before the senate and before the Agora in order to show that his ancestors had been citizens for three generations, and had to swear to obey the laws. The first of the nine archons was called "the archon," and sometimes the Archon Eponymus, because he gave his name to the year in all public records. He had the care of minors and orphans, and had to superintend some of the festivals. The second archon was called the King Archon. Upon him chiefly devolved the care of the religious concerns of the people, in connection with which he had to act as prosecutor of murderers and offenders against religion. The third archon had the name of Polemarch, and was originally entrusted with the superintendence of military matters, though in later times his duties were chiefly confined to the protection and superintendence of the resident

aliens. The rest of the archons were called Thesmothetæ, and exercised a general supervision over the laws of the state.

Archytas, är-kī'tās, an ancient Greek, a native of Tarentum, a famous Pythagorean philosopher, renowned also as a truly wise man, a great mathematician, statesman, and general. He was the contemporary of Plato and flourished about 400–365 B.C., but the dates of his birth and death are unknown. The invention of the analytic method in mathematics is ascribed to him, as well as the solution of many geometrical and mechanical problems. He constructed various machines and automata, among the most celebrated of which was his flying pigeon. Plato is said to have borrowed some of his opinions from Archytas, and Aristotle also is said to have been indebted to him for the idea of his categories and some of his ethical opinions. These opinions, however, appear to depend on spurious writings, the real remains of Archytas being of inconsiderable value. Horace mentions him in one of his poems (Carm. i. 28) as having been drowned on the coast of Apulia.

Arcif'era (Latin, *arcus*, bow, + *ferre*, to bear, carry), a division of Anura, including the toads.

Arcis-Sur-Aube, är'se'sü'rōb', France, a town of the department of Aube on the river Aube. It is the birthplace of Danton, to whom a monument was erected here in 1886. In 1814 a battle was fought here between Napoleon and the allies in which the latter, with a much superior force, had the advantage and afterward marched to Paris. Pop. 2,841.

Ar'co, Austria, a town in the Tirol, not far from the Lake of Garda, on account of its situation and mild climate a favorite winter resort of invalids. Pop. 3,782.

Arcole, är'kō-lā, a village in North Italy, in the province and 15 miles southeast of the town of Verona, on the left bank of the Alpone, celebrated for the battles of 15, 16, and 17 Nov. 1796, fought between the French under Bonaparte and the Austrians in which the latter were defeated with great slaughter.

Arçon, är-sôṅ, **Jean Claude Eléonore d',** a French military engineer: b. Pontarlier, 1733; d. 1 July 1800. He was received into the military school at Mézières, 1754, and in the Seven Years' war he highly distinguished himself, particularly at the defense of Cassel in 1761. In 1780 he invented the floating batteries for the attack of Gibraltar, which, however, were destroyed by the red-hot shot of the besieged. At the invasion of Holland under Dumouriez (in 1793) he took several places, including Breda. He then went into retirement, where he wrote his important ‹Considérations Militaires et Politiques sur les Fortifications› (1795).

Arcona. See ARKONA.

Arcos de la Frontera, är'kōs dā la frōntā'rā, a town in Spain in the province of Cadiz, on the right bank of the Guadalete, which is here crossed by a stone bridge. The sandstone rock on which the town, in form of a bow, is placed, rises 570 feet above the level of the river, which surrounds it on three sides. The houses are mean looking; the streets paved, but generally steep and narrow; and the ancient walls and defenses are in a ruinous state. On the highest part of the rock stands the castle of the dukes of Arcos, partly in ruins. Pop. (1900) 15,700.

Ar'cot, är-kŏt', the name of two districts and a town of India within the presidency of Madras. North Arcot is an inland district with an area of 7,256 square miles. The country is partly flat and partly mountainous. Pop. 1,817,-814. South Arcot lies on the Bay of Bengal, and has two seaports, Cuddalor and Porto Novo. Pop. 1,814,738. The town of Arcot is in North Arcot, on the Palar, about 70 miles west-by-south of Madras. There is a military cantonment 3 miles distant. The town contains handsome mosques, a Nawab's palace in ruins, and the remains of an extensive fort. Arcot played an important part in the wars which resulted in the ascendency of the British in India. It was taken by Clive, 31 Aug. 1751, and heroically defended by him against an overwhelming force under Rajah Sahib. Pop. 11,000.

Arc'tic, a term applied to the North Pole, or the pole raised above our horizon, from the proximity of the constellation of the Bear, in Greek called *arktos*. The Arctic circle is an imaginary circle on the globe, parallel to the equator, and 23° 28' distant from the North Pole, from whence its name. This and its opposite, the Antarctic, are called the polar circles. Within these circles the sun does not set during a part of the year, and during a corresponding part does not rise.

Arc'tic Charr. See TROUT.

Arc'tic Re'gion, the name given to the region of land and water surrounding the North Pole, reaching on all sides to lat. 66° 32' N. The Arctic or North Polar circle touches the northern headlands of Iceland; cuts off the southern and narrowest portion of Greenland; crosses Fox Strait north of Hudson Bay, whence it goes over the American continent to Bering Strait. Thence it runs to Obdorsk at the mouth of the Obi; then, crossing northern Russia, the White Sea, and the Scandinavian peninsula, returns to Iceland.

Climate.— The most important facts now ascertained respecting the climate of the Arctic regions are, that the main line of extreme cold extends across the Polar Sea from the meridian of 90° W. to that of 130° E., reaching much farther on the Asiatic than on the American side, so that the winter temperature of Yakutsk (lat. 62° 2') is 7° F. lower than that of Rensselaer harbor, in Smith Sound (lat. 78° 37'). But the American limit of cold oscillates much less than the Asiatic, the summer temperature at Rensselaer harbor being but 62°, while at Yakutsk it is 95° F. above that of winter. This difference is due to the absorption of summer heat by the comparatively dry plains of Siberia, while on the North American continent the numerous lakes and inlets moderate the climate throughout the year. To this it may perhaps be added that Greenland, owing to its peculiar constitution and position, is to North America a source of refrigeration which has no counterpart in the eastern continent. This circumstance, and the humid atmosphere maintained by the numerous lakes, somewhat moderates the severity of the cold, but at the same time renders it somewhat more constant.

Arctic Ocean.—In its widest sense that portion of the ocean which extends from the Arc-

tic Circle (lat. 66° 32′ N.) to the North Pole, or more restrictedly from about lat. 70° N. Assuming the former limit, the Arctic Ocean is found entering deeply, in the form of gulfs, bays, etc., into the northern parts of the continents of Europe, Asia, and America. The principal of these indentations are the White Sea in Europe; Kara Sea, Gulfs of Obi and Yenisei in Siberia; and Baffin Bay in North America. It is united to the Pacific by Bering Strait, and to the Atlantic by a wide stretch of sea extending from Greenland to Norway. Among the principal islands of the Arctic Ocean are Greenland (at last proved to be an island) and east of Greenland the extensive group known under the name of Spitzbergen, the small island of Jan Mayen, and Iceland. West of Greenland and divide from it by Davis Strait and Baffin Bay there are a considerable number of islands of great size but little interest. North of Europe are the islands of Nova Zembla; and north from these Franz Josef Land, an archipelago as yet imperfectly known. The water of the Arctic Ocean is extremely pure, shells being distinctly visible at a great depth; it also presents rapid transitions of color, chiefly from ultramarine to olive-green, the latter variations of color being produced by myriads of minute animals belonging for the most part to the *Cœlenterata* and *Mollusca* classes. Many have adopted the belief in the existence of an open polar sea about the North Pole. But this belief is not supported by any positive evidence. Ice is nearly constant everywhere between Spitzbergen and the southern point of Greenland. This is called the main north ice. East of Spitzbergen and near Nova Zembla the sea is always beset, if not completely barred, by ice. In Baffin Bay and thence west to Bering Strait numerous expeditions have had a perpetual struggle with ice. The expedition of 1875–6 under Captain Nares, members of which reached a point 30 miles further north than had ever previously been attained, proceeding by way of Baffin Bay and Smith Sound, found no indications of an open polar sea. On the contrary the explorers found north of 82° 27′ a sea consisting of one unbroken sheet of old ice of immense thickness, which effectually barred the further progress of the vessels, while the ruggedness of the ice rendered it impossible to reach the pole by sledge. Nansen more recently found abundance of ice in the tract of sea crossed by him.

Arctic Current.— It seems certain that a current sets into the polar basin along the coasts of Norway and Lapland. It is probably the effect of prevalent southwest winds, though some call it a branch of the Gulf Stream. There is also a strong current running in at Bering Strait. On the other hand, along the east coast of Greenland and in Baffin's Bay the movement is generally south. In the numerous channels between Baffin Bay and Bering Strait the tides are regular but feeble; indeed, it seems possible to trace across Barrow Strait the line of neutralized or no tide, and this, there is reason to suspect, is also the line of comparatively permanent ice.

Minerals.— Valuable minerals, fossils, etc., have been discovered within these Arctic regions. In the archipelago north of the American continent excellent coal frequently occurs. The mineral cryolite is mined in Greenland and carried to the United States. Among other fossils the remains of large saurians are found in the Lias, which extends widely over the northern archipelago, and ammonites collected in abundance prove that in lat. 73° north there was once a tropical temperature. The group of islands opposite the mouth of the Lena, in lat. 73°, are little more than accumulations of fossil remains carried down by the river, and are annually visited for the purpose of digging fossil ivory.

Vegetation.— The plants peculiar to the frigid zone are stunted more by the dry winter winds than by short growing seasons and long winters. The reduction is confined to the limbs, as roots are as long and penetrate as far as in more temperate climates. The vegetation is widely distributed, the species found in North America being practically the same as those found in Europe and Asia, and since trees become more and more scarce as the Pole is approached, the prevalence of the tundra formation is characteristic of the region. In respect to distribution, arctic plants differ from alpine plants (q.v.) which though otherwise similar, especially in the census of cushion and rosette plants and plants with thick-skinned evergreen leaves, include many endemic species. Arctic perennials are noted for the high percentage of species that develop wintering flowering buds which burst into bloom early in the spring. In the Arctic zone, less than two thousand species have been described, among them very few trees. These are mostly stunted willows, junipers, and birches, and beyond their northern limits flowering plants, grasses, mosses, and lichens extend as far as man has penetrated. Commonest among the flowering species are crowfoots, potentillas, poppies, saxifrages, whitlow grass (*Draba*) and scurvy grass (*Cochlearia*). Thyme and angelica, growing in sheltered spots, are the only perfume-bearers.

The English expedition of 1875-76 found 20 or 30 species of phanerogamous plants between lat. 82° and 83°. From Churchill River on the west side of Hudson Bay (lat. 53°), the line limiting the forest runs constantly to the north of west till it reaches Norton Sound, a little south of Bering Strait, larch and poplar making their appearance as we go west. In Siberia, where the summer heat is greater, woods flourish to a much higher latitude within the Polar Circle. In the Scandinavian peninsula the red pine reaches lat. 69°, the Scotch fir 70°, the birch 71°. Animal life is by no means deficient within the Polar Circle. Species indeed are few, but the individuals are extremely numerous. The proof of this is to be found in the immense number of skins of fur-bearing animals, eider ducks, seals, walrus, etc., annually supplied to commerce. Recent expeditions have found the usual arctic quadrupeds and birds as far north as the land extended. How far north the cetaceans reach is doubtful. See Distribution of Animals.

Notwithstanding this apparent abundance, the human being has in general a severe struggle for subsistence beyond 64° N. lat., although traces of Eskimos have been found as far north as 81° 52′. The Eskimos who inhabit Greenland and the extreme north of America have a hard life of it, often pressed, and not seldom cut off, by famine. Under their rigorous skies the resources derivable from the surrounding abundance of animal life can support

only a handful of men. Even in Siberia, where the reindeer trained to the sledge, and the great rivers frozen throughout the winter, add so greatly to the facilities of intercourse or emigration, whole communities are frequently cut off by famine or disease. Yet we see Europeans settled under the parallel of 73° at Upernavik in Greenland, of 72° 2′ at Ustyarsk in Siberia, and of 70° 40′ at Hammerfest in Norway, and Europeans have wintered far north of this. The settlements in Greenland, northern Siberia, Kamchatka, and the Hudson Bay territories are all more or less connected by trade with southern countries, whence they derive their power of endurance; and from the constant care required in order to guard against the consequences of the severe climate it is evident that to man the support of life within the Polar Circle must ever be difficult and precarious. Nevertheless, owing to the abundance of lower animal life, men have visited these regions for centuries to gather the exceedingly rich harvests of furs and oil.

Arctic Exploration.— See POLAR RESEARCH. The following are the farthest points of north latitude reached by Arctic explorers up to the present date: 1607, Hudson, 80° 23′; 1773, Phipps, 80° 48′; 1806, Scoresby, 81° 12′ 42″; 1827, Parry, 82° 50′; 1874, Meyer (on land), 82°; 1875, Markham and Parr (Nares' expedition), 83° 20′ 26″; 1876, Payer, 83° 07′; 1884, Lockwood (Greely's party), 83° 24′; 1896, Nansen, 86° 14′; 1900, Abruzzi, 86° 33′.

Bibliography.— Conway, 'The First Crossing of Spitzbergen'; Greely, 'Arctic Service'; 'Handbook of Arctic Discovery'; and 'Report on the Proceedings of the United States Expedition to Lady Franklin Bay'; Hayes, 'Arctic Boat Journey'; Jackson, 'A Thousand Days in the Arctic'; and 'The Great Frozen Land'; Jones, T., 'Natural History, Geology, and Physics of Greenland and Adjacent Regions'; Kane, 'Arctic Explorations, the Second Expedition in Search of Sir John Franklin'; Nansen, 'Farthest North'; Peary, 'Northward Over the Great Ice'; Ray, 'Report of the Expedition to Point Barrow'; Wright, 'Greenland Ice Fields and Life in the North Atlantic.'

Arctu'rus, a fixed star of the first magnitude in the constellation of Boötes, and thought by some to be one of the largest of the fixed stars. It has a large proper motion, and is a noticeable object in the northern heavens.

Ar'cus Seni'lis, a term applied to a white or grayish white rim on the outer edge of the cornea, due to the infiltration of a finely granular hyaline substance, heretofore thought to be a form of fatty degeneration. This is probably not the case, since the infiltration material has no relation to the corneal cells. It is more probably a condition due to changes in the blood vessels of the cornea and is frequently a result of old age. It is a normal phenomenon, however, occurring sometimes in perfectly healthy people, and there is no invariable relationship to fatty degeneration of the blood vessels, heart, or other organ.

Ardagh, är'dä, **Sir John Charles,** an English military officer: b. 1840. He entered the Royal Engineer Corps in 1859; and became major-general in 1898. He attended the Conference of Constantinople, Congress of Berlin, Bulgarian Boundary Commission, and the Peace Conference at The Hague, in 1899, and was for many years director of military intelligence in the British war office.

Ardahan, är'da-hän', a village in the portion of Turkish Armenia ceded in 1878 to Russia, 35 miles northwest of Kars. Its position gives it strategic importance. Its fortress was dismantled by the Russians in the war of 1854-6; in 1878 the Berlin Congress sanctioned the cession to Russia of Ardahan, which had been captured early in the war.

Arditi, är-dē'te, **Luigi,** an Italian musician and composer: b. Piedmont, 16 July 1822; d. Hove, Sussex, 1 May 1903. Famous first as a violinist, then as a conductor, he went to London in 1857, and from that year till 1878 was musical director at Her Majesty's Theatre. He has conducted Italian opera and concerts in places as remote from one another as New York and Constantinople; has published the operas 'I Briganti' (1841); and 'La Spia' (1856); and is known as author of much popular music — songs, violin duets and waltzes, such as 'Il Bacio.' He published his 'Reminiscences' in 1896.

Ard'more, Indian Territory, a city of the Chickasaws, on the Gulf, Colo. & Santa Fe, and Choctaw, Okla. & Gulf R.R.'s, about 20 miles north of the Red River. It is the seat of Hargrove College. Its commercial interests are cotton, coal, and asphalt. Pop. (1900) 5,681.

Are'ca, the designation of a genus of palms, possessing pinnate leaves, a double membranous sheath containing its bunches of flowers; fruit a one-seeded berry or drupe, with a fibrous rind. To this genus belongs the betel-nut or pinang palm (*A. cathecu*), a native of the East Indies, and cultivated there in many varieties. It is a very beautiful palm, with a slender stem often 40 or 50 feet high. Its nuts, called betel-nuts, are rolled into a leaf of the betel-pepper along with a little lime, and are then chewed. The nut contains at least four alkaloids, Arecoline, Arecaïdine, Arecaïne, and Guvacine, the former alone having known active properties. Arecoline is an active taeniacide and is widely used in veterinary practice for the treatment of tape worms. It is also an active cathartic and mydriatic. In the latter case it is extensively used as a stimulant. Another palm of this genus is the cabbage palm (*A. oleracea*), one of the most beautiful and stately of the palm tribe, with a stem rising often to the height of 200 feet, terminated by a graceful plume of waving feathery foliage. It is a native of Jamaica and other West India Islands. The so-called cabbage is the terminal leaf-bud, which is very tender and delicious, either raw or boiled. Its removal, however, kills the tree.

Arecibo, ä'rā-sē'bō, an important commercial town of Porto Rico; on the northern coast; facing the Atlantic Ocean; 50 miles west of San Juan. It resembles ordinary Spanish towns in having a plaza, surrounded by the church and other public buildings, in the centre, with streets running from it in right angles, forming regular squares. The buildings are of wood and brick. The harbor is poor, being exposed to the full force of the ocean, and having no nat-

ural or artificial protection. Imports and exports can be handled only by twice lightering. Tributary to the town is a district of about 30,000 inhabitants. Pop. (1903) about 12,000.

Ar'ena'ceous Rocks, the name applied to a petrographic division including loose sands and gravels, sandstone, conglomerate, quartzites and such rocks as are mainly composed of quartz particles. They are of mechanical origin, being derived from disintegration of pre-existing strata and removal and deposition of the materials by wind or water. The grains are generally waterworn and rounded; in some cases, however, they are more or less angular, or rounded and angular grains occur commingled. In older deposits, the grains of sand are bound together by silicious, calcareous, argillaceous, or ferruginous cements. It is seldom that a rock is composed of quartzose materials alone; grains or particles of other mineral substances are frequently mingled with the grains of quartz. Silvery flakes of mica are seldom absent; often occurring in layers parallel to the planes of stratification, thus causing the rock to split into thin slabs, and exposing a glittering surface. These are called micaceous sandstones. When grains of feldspar occur, the rock is a feldspathic sandstone. Often large quantities of calcareous matter, either as cement or as distinct grains occur; and these are called calcareous sandstones. In like manner we have silicious and ferruginous sandstones, when silica and oxid of iron are conspicuously present as cementing or binding materials. Clay and carbonaceous matter, when plentifully diffused through the rock, give rise to argillaceous, carbonaceous and bituminous sandstones. Greensand, or glauconitic sandstone, is a rock containing abundant grains of the dirty greenish mineral called glauconite. Arkose is a sandstone composed of disintegrated granite; volcanic sandstone, trappean sandstone, etc., being composed of disintegrated igneous rocks. The presence of lime can always be detected by the effervescence which takes place on the application of hydrochloric or other acid. A sandstone of homogeneous composition, which may be worked freely in any direction, is called freestone or liver rock. Flagstone is a sandstone capable of being split into thin beds or flags along the planes of deposition. When the sandstone is coarse-grained, it is usually called grit. If it contain, more or less abundantly, grains large enough to be called pebbles, the sandstone is said to be conglomeratic; and if the pebbles or stones be angular, the rock is described as a brecciiform sandstone. Coarse-grained grits and pebbly or conglomeratic sandstones pass into conglomerate or puddingstone, which consists of a mass of various sized water-worn stones. Brecciiform sandstones frequently pass into breccia, an aggregate of angular and sub-angular fragments. Graywacke is an argillaceous sandstone, more or less altered and sometimes semicrystalline, met with among palæozoic formations.

Arenales, ä'rā-nä'lĕs, **Juan Antonio Alvarez de**, a Peruvian patriot: b. 1775; d. 1825. When the Spanish army invaded Peru, Arenales led a body of troops against them by a long circuitous route, and defeated Marshal O'Reilly, whom he made prisoner, 6 Dec. 1820.

Ar'ena'ria, the name given to a genus of plants of the sandworts, of the *Caryophyllacaæ* or pink family. They number upward of 200 species, and are usually low-tufted herbs with white flowers. They are very common along the American sea-coast and in sandy places throughout the States north of the Ohio River. Several species are alpine or sub-alpine in habit and are found on the summits of the Eastern Appalachian. Of these the mountain sandwort (*A. Groenlandria*) is best known.

Areng' Palm, the name of a palm, formerly called *Areng saccharifera*, but now more generally denominated *Saguerus saccharifer*. It belongs to the section *Cocoinæ*, grows wild in the islands of southern Asia, and is cultivated in India. It furnishes sago and wine, while its fibres are manufactured into ropes.

Ar'eop'agus, the designation of the oldest Athenian court of justice. It obtained its name from its place of meeting, on the Hill of Ares (Mars), near the citadel. Its establishment is ascribed by some to Cecrops, by others to Solon; from the latter, however, it seems to have only received a better constitution and more important privileges, and it is probable that it existed from very remote times. Of how many members it consisted is not now known. A seat in it was held for life. The members were men who in their former capacity of archons had rendered themselves worthy of this honor by the honest and diligent execution of their office, and whose character and conduct had been subjected to a particular examination. Aristides called the Areopagus the most sacred tribunal of Greece, and Demosthenes assures us that they never passed a sentence in which both parties did not concur. Crimes tried before this tribunal were wilful murder, poisoning, robbery, arson, dissoluteness of morals, and innovations in the state and in religion; at the same time it took care of helpless orphans. The other states of Greece sometimes submitted their disputes to the judgment of the Areopagus. Its meetings were held in the open air and in the night time. After the investigation of a case the votes were collected. In the time of Pericles its political influence was materially lessened, but it continued a much venerated assemblage, and in Roman times its decisions still commanded respect. The Apostle Paul is sometimes thought to have been brought before this ancient court, but it is more likely that his famous address on Mars Hill was before an asemblage of philosophers there. See Botsford, 'The Athenian Constitution' (1893).

Arequipa, ä'rā-kē'pa, a city of Peru, the capital of a department of the same name. It lies in a fertile valley 200 miles south of Cuzco, at the height of 7,850 feet above the sea. Prior to the earthquake of 13 Aug. 1868, which did not leave a single house habitable, it was one of the best-built towns of South America. Behind it rise three lofty mountains, one of which, called the volcano of Arequipa, or Peak of El Mistè, is one of the most elevated summits of the Andes, having a height which Pentland estimates at 20,328 feet. It contains a cathedral, a college, a hospital, nunneries, convents, etc. Near at hand Harvard University has an observatory, at an altitude of over 8,000 feet. It is subject to frequent earthquakes, but this evil seems to be overbalanced by the mildness of the climate, and the beauty and fertility of

the country round about. Islav was formerly the port of Arequipa, but it has been superseded by the neighboring port of Mollendo, connected by railway with Arequipa. Pop. (1901) 35,000.

Argall, Sir **Samuel**, seaman and American colonial official: b. Walthamstow, Essex, England; d. 24 Jan. 1626. He was a type of the founders of English colonial dominion — energetic, resourceful and masterful; his further repute as a sort of unprincipled buccaneer and tyrant is due to sentiment and partisanship. In May 1609, he was sent with a small barque to the new settlement at Jamestown, Va., to trade and fish on behoof of the owner. He seems to have found a shorter route than usual, and soon established a reputation for unprecedentedly quick passages. The next year he took out Lord Delawarr to Jamestown, arriving just in time to prevent the entire colony, with the governor, Sir Thomas Dale, leaving for Newfoundland to avoid starvation. He was sent to the Bermudas for swine to replace those the colonists had eaten up, but was driven by storms to Cape Cod, where he found good fishing and returned in August; established a corn trade with the Indians above Jamestown, and early in 1611 returned to England with Delawarr, whose health was bad. In September 1621, he was again at Jamestown after the then swift passage of 51 days, and the rest of the year he and Dale spent in corn-hunting among the Indians. Powhatan had a number of English prisoners in his hands, and a quantity of weapons and implements; and Argall, hearing that the chieftain's daughter Pocahontas was with her uncle "Powtownec" (Potomac), had the happy thought of securing her to exchange against them, a feat accomplished by threats and the offer of a copper kettle to her uncle. The stock denunciation of him for this "nefarious treachery" is best answered by the fact that no one was harmed, all parties were benefited, and a most desirable aim was achieved. Pocahontas herself considered it a piece of rare good fortune, would not leave the whites, and soon after married one of them, while the prisoners were released, and peace restored to the colony. Argall handed her over to Sir Thomas Gates and explored the east shore of Chesapeake Bay, fishing and trading. Later in the year he was sent with a vessel of 14 guns to destroy the French settlements on the north coast, regarded as infringing on the Virginia patent. He captured Mount Desert, St. Croix, and Port Royal (N. S.), carried off the settlers as prisoners to Jamestown, and on the way forced the commandant at New Amsterdam to recognize English suzerainty by hauling down the Dutch flag and running up the English. In 1614 he sailed for England, and was put on his defense for these high-handed acts, but completely justified himself. In May 1617, he was made deputy-governor of Virginia, and remained two years in a broil with part of the citizens, but justified by others. He was accused of illegal trade with the West Indies, and repeatedly ordered to return to England for trial, a command which he ignored for a time, possibly in reliance on the Earl of Warwick, who financed and shared his ventures. In 1620 he served against the Algerine pirates with a 24-gun merchant vessel, under Sir Robert Mansell. He was knighted in 1622. In 1625 he was admiral of a squadron cruising after a hostile Dunkirk fleet, and took some prizes. On 3 October of that year he embarked with the squadron in the expedition against Cadiz under Lord Wimbledon, with Lord Essex on board as vice-admiral and commander of land forces; Argall's flagship was the Swiftsure. He reported the fortress too strong to be taken without a siege, the merchant vessels were ill supplied and unpaid, and after waiting till December for relief from Charles I. they went home. Argall died the next month, it was said from a broken heart because the captain of the Swiftsure was "very backward and cross" to him. (Argall's own narrative comes down to 12 May 1613.)

Argenteuil, är-zhän-tė-y, a town in France, on the right bank of the Seine, seven miles below Paris. It supplies much wine, fruit, and vegetables for the Parisian market. The famous Héloïse was abbess of its now ruined priory from 1120. Pop. (1896) 15,126.

Argentina, är'jĕn-tē'na, or the Argentine Republic, the second in size of the South American countries, extends from Bolivia, in the torrid zone, to Cape Horn, in the frigid zone. A just idea of its great length and climatic range may be given by comparison with the United States. The distance from its northern boundary to the equator is much less than from the equator to Florida; the territory of Tierra del Fuego is as near to the South Pole as Prince of Wales Island, Alaska, is to the North Pole. In its tropical north are valuable mines and forests of hardwoods; in the extreme south the collecting and storing of natural ice is a profitable industry. All the central provinces and territories have the climate of the temperate zone, and lie in one vast plain stretching from the Andes to the Atlantic. Above Buenos Ayres, however, the eastern limit of Argentina is not the ocean, but a river system exceeding in volume that of the Mississippi,— the Paraná and Uruguay rivers furnishing an outlet for the products of the region bordering on Uruguay, Brazil, and Paraguay, and finally uniting in the great Rio de la Plata.

History.— A Spanish captain named Juan de Solis discovered the Rio de la Plata several years before Magellan saw it (1520), and, according to the account of Pigafetta, one of Magellan's companions, the "gigantic natives called canibali ate De Solis and 60 men who had gone to discover land, and trusted too much to them." Again, in 1535, the Indians destroyed a colony that Pedro de Mendoza attempted to establish on the site of the modern city of Buenos Ayres, no permanent settlement being made at that place before 1580. In 1661 the king of Spain created a high court in Buenos Ayres, and appointed a governor and captain-general for the provinces of the Rio de la Plata. The provinces increased in importance to such an extent during the century which followed that in 1773 the King's representative became a viceroy. British forces, sent to capture Buenos Ayres in 1806 and 1808, were defeated by the natives, unaided by the viceroy; the resignation of the latter was demanded on 25 May 1810, and the patriotic movement did not cease until independence was achieved. A junta composed of nine members, assuming the reins of government, despatched revolutionary expeditions into Paraguay, the northern provinces of Argentina and Alto Peru (now Bolivia); for it was evident not only that the power of Spain

could not be broken without the united efforts of the patriots who were scattered throughout the southern portion of the continent, but also that Argentina was the natural leader in such enterprises.

During seven years the issue remained in doubt: all the advantages that the Argentine general, Belgrano, gained at first seemed to be lost when he suffered defeat at the hands of Gen. Peguela in Dec. 1813. But six months afterward the nearest and most threatening Spanish stronghold, the fortress of Montevideo, was captured. Independence was declared, 9 July 1816, at a congress representing the different provinces; then Gen. San Martin led across the Andes a force of 5,000 Argentina soldiers recruited largely from the hardy plainsmen and cowboys (*gauchos*). His little army of "rough riders," by defeating the Spanish troops in the battle of Chacabuco, gave independence to the Chilean people. San Martin was also successful against the Spaniards in Peru, entering Lima as a liberator in 1821. Though urged to accept the civil government of the countries he had freed, this soldier of splendid ability refused the rewards, honors, or offices in civil life, which those men fulfilling similar missions in other lands have almost without exception consented to receive. Moreover, the attitude of the Argentine revolutionists in general was characterized by disinterestedness in this crisis; and subsequently, when Brazil sought to annex Uruguay, Argentina appeared as the champion of the smaller state. A war lasting three years (1825–8) was required to convince Brazil that Uruguay's independence must be guaranteed by both her great neighbors. But the bright prospects of Argentina herself suffered eclipse from 1829 to 1852. Juan Manuel de Rosas succeeded in establishing a virtual dictatorship, maintaining himself in power despite repeated attempts to oust him, until the year last mentioned, when he was defeated by Gen. Urquiza in the battle of Caseros. Taught by experience, the people now resolved to safeguard their rights and privileges for the future. A constitution closely resembling that of the United States (though president and vice-president hold office for six years, and senators for nine, and other interesting adaptations were made) was promulgated 25 May 1853. In 1862–8 we see Argentina, allied with Brazil and Uruguay, engaged in resisting Paraguay's claim to ownership of the territory El Chaco. The allies were successful in the field; nevertheless the dispute was referred to the President of the United States, Mr. Hayes, as arbitrator. Such respect for law, as superior to force of arms, was shown during Gen. Bartolomé Mitre's term of office. Significant administrations were those of Señor Sarmiento, who succeeded Gen. Mitre, of Señor Avellaneda, and of Gen. Roca. The first of these was familiar with the United States, where he had resided as Argentina's diplomatic representative, and the efforts he made to bring the institutions of his own country into harmony with those he had studied at Washington — especially in the matter of popular education — helped progressive Argentina to earn the title of the "Yankee-land of South America." General Roca, as minister of war during Avellaneda's presidency, extended the southern frontier so that it included a large part of Patagonia; his first term of office as President is memorable on account of the extension of the railway system, the erection of many public school buildings, the formal selection of the city of Buenos Ayres as the capital of the republic, and the foundation of the city of La Plata (1882). A financial crisis that afflicted the country caused the resignation of President Celman, who succeeded Gen. Roca in 1886. The people, convinced that the President's policy was responsible for the "hard times," practically forced him out of office by the pressure of public opinion. This may be regarded as a striking demonstration of the power of unfeigned and non-partisan disapproval, inasmuch as a revolutionary movement was first attempted and proved a failure. Vice-President Pelligrini brought so much skill to the tasks thus devolving upon him as Celman's successor, that he guided the country safely out of its troubles. The question of limits with Bolivia, Chile, and Brazil continuing to occupy the attention of the Argentine foreign office during the presidency of Peña (succeeding Pelligrini, 12 Oct. 1892), the preference for deciding boundary disputes by arbitration without a preliminary war, was strongly manifested, as was but natural after the El Chaco affair. President Roca (re-elected) was able to report the satisfactory financial conditions in 1902, to which reference will presently be made; also the decision of the question of the boundary between the Argentine Republic and Chile by the award of the arbitrator, King Edward VII., dated at the court of St. James, 20 Nov. 1902.

Immigration and Population.— The Constitution of Argentina provided that "The federal government shall encourage European immigration, and shall not restrict . . . the entry . . . of foreigners who come for the purpose of engaging in the cultivation of the soil," etc. The greater part of the land of the republic being devoted to grazing and the production of live stock, while its value for agricultural purposes is still greater, immigrants have been attracted by a liberal policy which both the federal and provincial governments adopted: the former, in addition to free grants of land, has advanced capital (oxen, tools, etc., to the value of $1,000 for each farmer) to be paid back in five years. There were 125,951 immigrants in 1901, the nationalities represented being as follows: Italians, 58,314; French, 21,788; Spaniards, 18,066; Austrians, 2,714; Syrians, 2,159; Russians (chiefly Poles), 2,086. The area of lands under cultivation shows such an increase as might be expected — 17,174,250 acres in 1902, as against only 7,478,700 acres in 1880. The total population of the Republic 1 Jan. 1902, was 4,749,149.

The city of Buenos Ayres, with 821,291 inhabitants, ranks as the eleventh city of the world in respect to population.

Education.— For both boys and girls between the ages of 6 and 14 years education is compulsory and gratuitous. There is one school for each 1,000 inhabitants. Córdoba and Buenos Ayres have universities. Military and naval academies, a national observatory, trade schools, and an academy of mining engineers, have already been established, and it is the government's purpose to add to these practical

schools for the instruction of laborers in rural industries and forestry near the capital or principal city of each province. Primary education is under the direction of a national board of education, which has practically full control of the public schools and enjoys an income of its own. The matriculates in different grades in 1901 numbered 69,958 in the city of Buenos Ayres alone. There are more than 200 public libraries in the country, the government adding an equal sum to any endowment by private gift.

Public Spirit.— Enthusiasm for the public good and national advancement is an Argentine characteristic. One of the 20 daily newspapers published in Buenos Ayres devotes a large part of its costly building to public uses for the glory of the city. At its own expense it provides a free consulting room, where a physician and five assistants minister to the sick; a law office where indigent persons secure free legal advice; a museum of the products and manufactures of the republic; a library open to students without payment; a great hall for public meetings; a charming *salon des fêtes*, where literary, charitable, and scientific meetings are held: even a palatial suite of apartments for the reception of distinguished foreigners. The trait illustrated by this liberal undertaking differentiates the people of Argentina somewhat from other nations of the continent: yet they have their full share in the common Latin-American love of amusements.

Railways.— The enormous extent of flat country (Argentina's total area being 1,118,000 square miles), favors the construction of railways. More than 20 lines, having an extension of about 9,000 miles in the aggregate, are in actual working order, while a score of new lines are being built. The capital invested amounts to about $553,000,000 gold. Of the 20 lines completed before 1900, 16 were English and 4 belonged to the Argentine government. The accommodations for passengers are excellent. In December 1901, the Argentine Congress granted a concession for an important railway which is to cross the Territory of Misiones, form the connecting link between the Brazilian and Argentine systems, and constitute a section of the grand chain of railroads which will eventually traverse North and South America. The Buenos Ayres and Valparaiso Transandine Railway is the end of a long series of lines destined to be a fraternal as well as a commercial tie between the Chilean and Argentine republics. The telegraph lines of the republic have a length of 15,074 kilometres and represent an invested capital of about $5,000,000.

Sanitation.— The water-works and sewerage systems of the city of Buenos Ayres engaged the best engineering skill available. The cost of the latter even before 1890 was $34,000,000 gold. The city's death rate is 17 for every 1,000 inhabitants, as against 18.4 for the city of New York. Public hygiene is the object of government aid in the Argentine ports.

Capital City.— Whereas long ago the merchants of Seville sent every commodity to Buenos Ayres, the Argentine capital now takes little or nothing from Spain. It has lost its Spanish aspect, a preference being shown for the French style in architecture and the interior furnishings of the houses. The bustling activity in its business streets, the vitality, enterprise, and ambition of its inhabitants, are characteristically American. The foreign population numbers over 200,000, and the influence of German and English customs has also been felt. In fine, it is a cosmopolitan town; its people are not only devoted to the theatre and the race track, but are intelligent and much interested in the education of their children. Modern docks extending three miles along the city's front have been constructed at a cost of $25,000,000. Among the noteworthy buildings are the hall of justice, artillery arsenal, mint, stock exchange, Colon theatre, museum of natural history, and cathedral (begun in 1580; rebuilt in 1752). An English syndicate has acquired the concession of an underground electric road, to connect Victoria Place, at the centre of the city, with the Western Railroad station — a distance of about two and a half miles. Palermo Park, always beautiful, is especially so at night when illuminated by its arches of electric lights. The city and suburban street railway system has about 600 miles of track. It has been developed chiefly by English capital.

Provinces.— La Plata, a spacious, handsome city of 50,000 inhabitants, is the capital of the province of Buenos Ayres. The area of this province is greater than that of the State of New York; its population 1 Jan. 1902 was 1,140,067; its soil is a rich alluvium above clay — the latter being used largely in the manufacture of pottery. Almost the entire province is laid out in cattle farms, and immense quantities of salted beef, hides, and tallow are exported. It has been estimated that there are 200 sheep, 20 cows, and 6 horses to every inhabitant. The province of Entre Rios (population, 343,684) produces the best wheat. Córdoba province (population, 419,072) produces copper, silver, gold, marble, lime, etc., as well as cattle, horses, and sheep. In general we may say that the chief mining regions are near the northern and western boundaries of the republic. Thus, Jujuy, the most northwesterly province, has mines of gold, silver, copper, mercury, salt, and asphalt. Its capital, the city of Jujuy, though still a small place, has a complete system of educational institutions — public schools, normal schools, and a national college. It is connected with Buenos Ayres by railway. Other mining districts are: Province of Salta (area, 45,000 square miles; pop. 131,938), which produces kaolin, besides the minerals found in Jujuy; but hitherto less attention has been given to mining than to the cultivation of sugar-cane, tobacco, wheat, maize, and rice. Similarly the provinces of Catamarca, Rioja, and San Juan, which also border on Chile, have mountainous characteristics and abundant mineral products. Mining is the principal industry of San Luis. Especially interesting are the province and city of Tucumán — the former called "The Garden of the Republic," on account of the beauty of its scenery and the prosperity of its inhabitants; the latter, "The Cradle of the Republic," for the reason that the Congress which issued the declaration of independence held its sessions there. The products of this small province are oranges, lemons, timber, cheese, and leather; pop. 249,433. Other provinces that take their characteristics from the great plains (Pampas) are: Santiago del Estro (pop. 180,612), which has

but one hill in all its 31,500 square miles; Santa Fé (pop. 523,236, one third foreign), which also controls most of the export and import trade of the provinces north of Buenos Ayres. Its principal city is Rosario on the Paraná River. The province of Mendoza (pop. 141,431), is mountainous in its western part, with rich plains in the centre and east. Its products are wines, olives, grapes, figs, and the ordinary cereal crops. Oil wells have recently been discovered. In 1861 its capital was almost completely destroyed by an earthquake, and over 10,000 persons perished in the ruins. The new city of Mendoza has a national college, two normal schools, an agricultural school, and 20 public schools.

Rapid Industrial Development.— Up to the year 1875 Argentina's exports were limited to products of the pastoral industry, while the country was dependent upon other lands for all manufactured articles. But nearly all the important branches of human industry are represented in the period of development that began after the year just mentioned. To such an extent is this true that Argentina not only produces for home consumption a great variety of articles formerly imported, but actually exports such articles in large quantities. In Buenos Ayres alone there are nearly 8,000 industrial establishments, including those for spinning, for preparing hides, for working timber and metals, for cereals, for the manufacture of articles of glass and wax, chemical products, grocery products, liquors, cigars, etc. Factories for making chocolate have been started in various parts of the country, the product being so abundant and of such excellent quality that the importation of chocolate has almost ceased. Over 50,000 men are employed in the woodworking industry; 25,000 persons in the manufacture of boots and shoes; there are 17 hat factories, and cloth and underwear are produced at a number of mills.

Cattle and Sheep.— The greatest industry, however, is still the raising of cattle and sheep. Argentina has more sheep than Australia, and exports 240,000 tons of wool annually. In 1899 there were 22,000,000 cattle, 5,000,000 horses and mules, and 85,000,000 sheep distributed among the various provinces. The general exportation of cattle products in that year was valued at $115,547,000 gold, or more than 62 per cent of the total exports of the country. Argentina's chief meat market is England. The total value of all kinds of cattle was estimated at $1,136,780,411 in 1895, and since that time the horned cattle, horses, and sheep have increased in numbers and improved in quality through the importation of full-blooded animals from the first breeders of Europe and the United States. By the year 1902 the dairy industry had become important: there were 523 dairies with four or five thousand cows in the largest establishments, and 1,300 tons of butter were sent abroad, chiefly to England.

Grain.— Before the war with Paraguay, the people of Argentina imported nearly all their flour from Chile, but during that war farmers found a good market for their products, and the cultivation of grain was encouraged. Wheat is now one of the chief articles of export to Europe. Owing to exceptionally advantageous conditions Argentine crops of wheat and Indian corn represented a per capita production of 42.33 bushels, against 42 in the United States and Denmark, 30 in Canada, 23 in Sweden, 20 in Russia, 19 in France, and 8 in Great Britain. The value in gold of the various Argentine harvests in 1899 was: wheat, $95,000,000; Indian corn, $23,000,000; lucern, $90,000,000; flax, $27,000,000; vineyards, $9,500,000; sugar-cane, $4,750,000; tobacco, $3,900,000; other cultures, $21,560,000.

Immense forests, producing varieties of hard wood which are useful for building and cabinet-making, are found in the provinces of Santiago del Estero, Salta, Tucumán, and Corrientes, as well as on the national lands of Chaco, Formosa, and Misiones. During the years 1895–99 about 8,000 tons of wood were exported, while the production increased greatly during 1900. Exploitation of these wooded regions is facilitated by a system of rivers which all flow into Rio Paraná. Each season witnesses, not only the development of the standard industries which have been mentioned, but the establishment of new enterprises. Among the latter the silk-worm culture in Santa Fé province and the evaporated fruit-industry in Córdoba province may be mentioned as recent examples. The largest items among imports from the United States are agricultural implements (amounting to about $2,000,000 in 1902) and mineral oils, refined or manufactured. During the years 1896–1901, inclusive, the total values of exports to and from the United States were as follows:

Year	Imports from U. S.	Exports to U. S.
Year 1896,	Amt. $8,361,195	Amt. $7,072,825
" 1897,	" 5,942,912	" 14,759,730
" 1898,	" 8,066,573	" 5,723,969
" 1899,	" 12,378,866	" 6,164,961
" 1900,	" 14,852,813	" 8,441,495
" 1901,	" 13,174,140	" 9,950,862

The total foreign trade of Argentina is on a vastly greater scale. At the beginning of this century its exports to all countries (taking the average of several years) amounted to about $175,000,000 annually; its imports from all countries being about $114,000,000 annually. During the first six months of 1902, Argentina's total exports rose to $105,203,781, and the total value of imports was less than half that amount. These figures show, first, the relatively small interchange of products between the United States and Argentina, and, second, the enormous balance of trade in favor of the Argentine Republic.

Financial Situation.— The Bankers' Clearing House of Buenos Ayres in 1900 showed transactions aggregating 3,402,660,743.12 pesos (pesos = $0.965), although several of the banks do not settle their operations through the clearing house. The financial situation of the republic in 1901 was fairly encouraging, the government's receipts being $38,244,638 in gold and $62,341,306 in paper currency, and the expenditures somewhat less. On the last day of 1901, the consolidated interior debt amounted to $17,863,000 in gold and $83,610,983 in paper currency. The foreign debt amounted to $386,451,295 in gold, but of this total the sum of $46,000,000 was owed by individual provinces.

Marrion Wilcox,
Authority on Latin-America.

Ar'gentine, Kansas, a city in Wyandotte County, about three miles from Kansas City, on the Atchison, T. & St. Fe. R.R. It has extensive

smelting interests, and several grain elevators. Pop. (1900) 5,875.

Ar'gentine, the name of a group of small smelt-like fishes, living in the open seas of the north temperate zone, and distinguished by the brilliant, silvery appearance of their scales. Some ascend rivers to deposit their spawn, where they are caught in large quantities and eaten as a delicacy.

Argentite (from the Latin, *argentum*, "silver"), a native sulphide of silver, belonging in the galena group, crystallizing in the isometric system and having the formula Ag_2S. It is opaque and has a metallic lustre and a dark, leaden gray color. Its hardness is from 2 to 2.5, and its specific gravity is about 7.3. Argentite occurs in many countries and when found in quantity is a valuable ore of silver. It occurs in crystals (often distorted), massive, in crusts, and in thread-like aggregates. Choice specimens occur in the silver mines of Joachimsthal, Bohemia, and Freiberg, Saxony; in Bolivia, Chili, and Peru, and notably at Batopilas, Mexico; also in many silver mines in Colorado, Nevada, and elsewhere in the United States. Argentite is often called "silver glance" by miners.

Argentoratum, an Old Celtic word, meaning "atones of Argantos," the Old Roman name for Strasburg.

Ar'gilla'ceous Rocks, a petrographic division including those rocks that are largely composed of clay. They owe their origin to the disintegration and decomposition of other rocks and hence are always of secondary nature. Among the common varieties belonging to this class are ordinary brick-clay, fire-clay, potter's-clay, kaolin, mudstone, shale, and marl (qq.v.). Clay rocks are easily influenced by metamorphic agencies, yielding shale, mica-schist, graywacke, and other hard rocks. See SEDIMENTARY ROCKS.

Arginusæ, är'jĭ-nū'sē, the name of several small islands southeast of the Island of Lesbos, a province of Asia Minor. In their vicinity the Athenians, under Conon, 406 B.C., defeated the Spartans under Collicratidos, in a hard-contested naval battle.

Ar'gives, or **Argivi,** the inhabitants of Argos; a term used by Homer and other ancient authors as a generic appellation for all Greeks.

Ar'go, the important southern constellation of the Ship, which is nearly 75 degrees in length, and contains over 800 stars visible to the naked eye.

Ar'go. See ARGONAUTS.

Argob, the name of a district in Bashan, referred to in Deut. iii. 4, as the kingdom of Og, and containing threescore walled cities. Its precise location has not been determined.

Ar'gol (origin of the word unknown), a term applied to the crude acid tartrate (or bitartrate) of potassium, as deposited on the sides of the vats in which wine is fermenting. It exists in the grapes from which the wine is made, but is precipitated from solution in the vats by the alcohol formed during the fermentation. Like many other precipitates, argol brings down more or less of the coloring matter in the solution from which it is deposited, and it is white or red, according to the color of the wine from which it is formed. When purified by re-crystallization from its solution in hot water, argol is known in commerce as "cream of tartar." The purified salt is extensively used in baking powders and to a lesser extent in medicine.

Ar'golis, a peninsular state of ancient Greece; between the bays of Nauplia and Ægina, now forming with Corinth, a monarchy or department. Argolis was the eastern region of Peloponnesus, and its inhabitants were often called Argives. According to the monuments of Greek mythology, Argolis was peculiarly rich, and early cultivated. Here reigned Pelops, an emigrant from Asia Minor, from whom the peninsula derives its name. It was afterward the seat of government of Atreus and Agamemnon, Adrastus, Eurystheus, and Diomedes. In the earliest times it was divided into the small kingdoms of Argos, Mycenæ, Tiryns, Trœzene, Hermione, and Epidaurus, which afterward formed free states. The chief city, Argos, has retained its name since 1800 B.C. Its inhabitants were renowned for their love of the fine arts, particularly of music. Some vestiges remain of its ancient splendor, and it has at present about 9,000 inhabitants. Near it is the capital of Argolis, Nauplia, or Napoli di Romania, with an excellent harbor, and the most important fortress of the peninsula. On the site of the present village of Castri, on the Ægean Sea, formerly lay the city Hermione; opposite is the island of Hydra. Pop. of province of Argolis and Corinth (1896) 157,578.

Ar'gon (Greek, "inactive," in allusion to its entire lack of chemical affinity), a gaseous substance, presumably an element, discovered in the earth's atmosphere in 1894 by Lord Rayleigh and Prof. William Ramsay. For some years previous to this discovery, Lord Rayleigh had been engaged in a careful determination of the densities of certain gases, and consistent results had been obtained for all of them save nitrogen. This gas, when prepared from air by the abstraction of all other known components, was found to be heavier by about one part in 200, than the nitrogen prepared from ammonia. There could be no doubt about the reality of the difference, because the same experimental methods, when applied to other gases, gave results that were consistent with one another to about one part in 10,000. In studying the cause of the discrepancy, Lord Rayleigh prepared nitrogen from ammonium nitrite, from urea, and from nitric and nitrous oxides: and found that all specimens of the gas that were prepared from nitrogen compounds agree with one another in density, but that the specimens of nitrogen that he prepared from air were uniformly and consistently heavier, by the same constant amount of one part in 200. Provisionally, therefore, he recognized two kinds of nitrogen, which he called "chemical nitrogen" and "atmospheric nitrogen," respectively, to indicate the sources whence they were obtained. He then published a letter in 'Nature,' narrating these facts, and calling for suggestions from chemists as to the cause of the systematic difference in density. No ideas of value were elicited. The possibility that

"chemical" nitrogen might be contaminated with hydrogen, and that the experimental methods failed to eliminate the last traces of this very light gas, was tested by adding hydrogen to "atmospheric" nitrogen, and then submitting the mixture to the same process employed for removing any hydrogen that might have existed in the "chemical" nitrogen. If the hydrogen theory of the discrepancy had been true, it would have been found that "atmospheric" nitrogen, when treated in this way, would ultimately agree in density with "chemical" nitrogen; but the test showed that "atmospheric" nitrogen, after the addition and subsequent removal of hydrogen, returned to its original state of higher density, thus proving the adequacy of the experimental methods, and disproving the hypothesis that the difference in density was due to hydrogen. The suggestion was also made that the "atmospheric" nitrogen had partly polymerized into an allotropic state analogous to ozone, or that the "chemical" nitrogen had partially dissociated into monatomic molecules. These possibilities were tested by subjecting both kinds of nitrogen to the action of the silent electric discharge, in an apparatus designed for the production of ozone from oxygen. It would certainly be expected that the difference in density would partially or wholly disappear under this treatment if there were any basis to the polymerization or dissociation hypotheses; but it was found that both kinds of nitrogen retained their initial densities, so that the original difference persisted undiminished in amount. Furthermore, if the lightness of "chemical" nitrogen were due to a partial dissociation induced by the method of preparation, it would be reasonable to expect that the molecules would re-combine in time with a resulting return of the density to that observed in "atmospheric" nitrogen. Specimens of "chemical" nitrogen that were allowed to stand for eight months, however, were found to retain their characteristic lightness. At this stage in the investigation, Prof. Ramsay asked permission to co-operate in the investigation, and his services were gladly accepted. The hypothesis was made that "chemical" nitrogen contains an unknown gas, *lighter* than true nitrogen; or that "atmospheric" nitrogen contains some similar gas that is *heavier* than true nitrogen. In spite of the many analyses that had been made of the air, it was thought more probable that the unknown gas would be found in "atmospheric" than in "chemical" nitrogen; and hence the experimenters turned their attention to the problem of removing "true" nitrogen from the "atmospheric" nitrogen, with the idea of obtaining a possible residuum, which would at least contain the unknown gas in concentrated form. For this purpose it was proposed to take advantage of the known fact that at a red heat nitrogen will combine with metallic magnesium, with the formation of magnesium nitride. "Atmospheric" nitrogen, carefully freed from all known impurities, was therefore passed through a long tube of hard glass filled with magnesium shavings and heated in a furnace. The first experiment of this sort was made in May 1894, and gave encouraging results, the "atmospheric" nitrogen showing a slight but unmistakable increase in density. A more elaborate experiment of the same sort followed, in which "atmospheric" nitrogen was caused to pass over hot magnesium for more than two weeks. By this means its density, originally about 14 (that of hydrogen being 1), was increased to 19.09, and the bulk of the gas under examination was diminished until not much more than one per cent of it remained. Plainly a great concentration of the unknown gas has been effected. To remove the last traces of true nitrogen, pure oxygen was next added, and the mixture exposed to a rain of electric sparks in the presence of caustic soda. When so treated the experimental gas contracted, indicating that the nitrogen was being withdrawn in the form of nitrate of sodium. When contraction was no longer noted, the nitrate of sodium and the excess of oxygen were removed, and it was found that the remaining gas had a density about 20 times as great as that of hydrogen. When subjected to the electric spark and examined by the spectroscope, this residual gas was found to exhibit certain characteristic groups of red and green lines that did not correspond to any element previously known. The experimenters, therefore, felt reasonably sure that a new element had been discovered, and this conclusion has been borne out by all subsequent investigations. The discovery of this element (to which the name "argon" and the chemical symbol "A" have been assigned), was formally announced to the public in Aug. 1895, and for it Lord Rayleigh and Prof. Ramsay were awarded the Hodgkins prize and also the grand prize of the Smithsonian Institution. See Air.

As it was found that air contains 0.937 of one per cent (by volume) of argon, it is natural to ask why the new element had escaped detection in the vast number of air-analyses that have been made in the past. The answer is that argon shows no chemical affinity whatever, and as nitrogen is also inert in comparison with most elements, the two were very easily confused. Chemists have almost invariably estimated the nitrogen of the air "by difference"; that is, by removing all such constituents as oxygen, carbon dioxid, and ammonia, and taking it for granted that the inert remainder is nitrogen. It might be thought that the spectroscope would betray the presence of argon, when the spectra of "atmospheric" and "chemical" nitrogen were compared; but the curious fact has been established that when argon and nitrogen are mixed, the argon does not reveal itself to the spectroscope unless the mixture contains at least 37 per cent of argon. Upon looking over the work that had been previously done upon air, it was found that Cavendish had isolated nearly pure argon as long ago as 1785, but without recognizing its real nature. Thus, knowing that air contains a considerable quantity of nitrogen, he raised the question whether all of the apparently nitrogenous part of the air "could be reduced to nitrous acid, or whether there was not a part of a different nature from the rest which would refuse to undergo that change." To decide this point he added excess of oxygen to air and passed electric sparks through the mixture (precisely as Rayleigh and Ramsay did) until no further diminution of volume occurred. He then removed the excess of oxygen, together with the oxids of nitrogen that had been formed, and found that only a small bubble remained unabsorbed, which, he says, was not more than

one one hundred and twentieth of the bulk of the original nitrogen. The bubble that he thus obtained and whose nature he did not further question must have been nearly pure argon.

Argon having been discovered, chemists at once undertook to ascertain its chemical properties, but here they met with an obstacle that has not yet been overcome, and which constitutes one of the strangest facts known to chemistry. It was found, namely, that argon cannot be made to enter into chemical combination with any substance whatsoever. Thus Rayleigh and Ramsay have stated that "argon does not combine with oxygen in presence of alkali under the influence of the electric discharge, nor with hydrogen in presence of acid or alkali, nor when sparked, nor with phosphorus at a bright red heat, nor with sulphur. Tellurium may be distilled in it and also sodium and potassium. Red hot sodium peroxid has no effect. Persulphids of sodium and calcium have no effect at a red heat. Platinum sponge does not absorb it. Aqua regia, bromine water, bromine and alkali, and potassium permanganate are all without influence. Mixtures of metallic sodium and silica, or of sodium and boric acid, are likewise without influence, and hence also nascent silicon and boron." Moissan further found that fluorin does not act upon it at any temperature. In short, it may be said that every reagent that the previous experience of chemists indicated as likely to combine with argon has been tried without success, and hence the chemical properties of the element (if, indeed, it has any such properties), are as yet quite unknown. Several announcements of the existence of compounds of argon have been made, but no really convincing evidence of such combination has been given. For example, Berthollet subjected a mixture of argon and benzene to the action of the silent electric discharge for a long time, and observed a diminution in the volume of the argon, which he attributed to its combination with the benzene. Benzene when treated in this way forms a resinous mass, which coats the walls of the tube, and it is not improbable that the small quantity of argon which disappears is held mechanically by the gummy deposit, either in solution or by absorption. At all events the original quantity of argon is restored, unchanged, by heating the resin. It cannot be positively affirmed that no compound of argon exists, but there is no previously known element (not even the metals of the platinum group) that could withstand the action of the substances whose activity has been exerted without effect upon argon. The only promising result that has yet been reached is that announced by Villard, who states that at 32° F., and at a pressure of 150 atmospheres, argon forms a crystalline hydrate with water, which dissociates again into argon and water at a pressure of 105 atmospheres. Even this result requires confirmation, since Villard did not really prove the presence of argon in the crystals that he obtained. Until some compound can be formed we shall therefore have to infer the atomic weight of argon from determinations of the density of the gas, taken in connection with Avogadro's law. The best determinations made up to the present time indicate that the density of argon is 19.80 times that of hydrogen. If the molecules of argon are diatomic, then 19.80 is the atomic weight of the element, but if they are monatomic, we must double this estimate and conclude that the atomic weight is 39.60. (See ATOMIC THEORY; also GASES, KINETIC THEORY OF.) To settle this doubtful point experiments were made to find the ratio of the two specific heats of the gas, and it was found that the specific heat of argon at constant pressure is about 1.65 times as great as the specific heat at constant volume. This indicates that the molecule of the gas contains but one atom, and hence it is necessary to conclude that the atomic weight of argon is 39.60, the atomic weight of hydrogen being taken as 1. Argon has been liquefied and solidified. Its critical temperature is 179° F. below zero, and its critical pressure is about 52.9 atmospheres. Liquid argon boils (under ordinary atmospheric pressure) at about 303° F. below zero, and at about 306° below zero it freezes. The density of liquid argon is about 1.212 times as great as that of water. Four other elements, associated with argon in the air and closely resembling it in properties, have been discovered as the result of researches suggested by the discovery of argon. They are called, respectively, helium, neon, krypton, and xenon (qq.v.). Hundreds of papers dealing with argon and the other gases just mentioned have appeared in the scientific periodicals, so that no bibliography of the subject can be attempted here. Ramsay's book, 'The Gases of the Atmosphere' (1896) gives an excellent account of the chemistry of the air, from the earliest times down to 1896. It must be remembered, however, that our knowledge of argon and its allies is growing rapidly, so that some of the statements that Ramsay makes can be no longer admitted to be true. For example, he states that helium (which had already been discovered when his book was written) does not occur in the air, but it has since been shown that it *is* a component of the air, forming from one to two one millionths of its bulk. Travers' 'The Experimental Study of Gases' may also be consulted with advantage.

Ar'gonaut, the appellation of an eight-armed oceanic cephalopod, closely allied to the octopus, and having the same power of swimming backward by forcing water through its funnel. Though called "paper nautilus" is is entirely different from the true nautilus (q.v.), and although, since the earliest days, it has been said to sail upon the surface of the ocean, in its shell as a boat, with two web-like arms spread for sails, this belief is pure fable. Argonauts remain in deep water except in spawning season, and then come to the surface only at night. The male is a naked octopod, and the "boat" of the female has no organic connection with her body, but is a mere receptacle for holding eggs, retained in place by the two dorsal arms, which are membranous and secrete it from their inner surfaces. It is not chambered like that of the true nautilus, but has a radially fluted, semi-transparent spiral shell, enveloping the body as far as the base of the tentacles, increasing in size with the growth of the animal, and attaining a length of six inches. The male is only about an inch in length; one of its very short arms is specialized into an organ of generation, called a "hectocotyle," which detaches itself from the male body, and, having independent locomotory powers, attaches itself to the

female, and in some manner unknown fertilizes the eggs. Only a single species is known (*A. hians*), representing the family *Argonautidæ*. See NAUTILUS.

Ar'gonauts, the name given in Greek legends to the sailors, who, in a ship called the Argo, made a hazardous voyage to Colchis under the leadership of Jason, in quest of the golden fleece. Jason's uncle Pelias had usurped the kingdom of Iolcos and would resign it only on condition that Jason should first bring from Colchis the golden fleece suspended in a consecrated grove at Colchis. Among Jason's companions were Hercules, Castor and Pollux, Peleus, Admetus, Meleager, Orpheus, Telamon, Theseus, and his friend Pirithous, Hylas, and Lynceus. Having sailed from the promontory of Magnesia, in Thessaly, they reached the harbor of Lemnos, where they remained two years. The women of Lemnos, instigated by the offended Aphrodite (Venus), had slain all the males among them, except Thoas, and they detained among them the welcome strangers. At length they proceeded to the Troad, where Hylas and Hercules were left behind. After various adventures they approached the dreaded Symplegades, rocks which closed together and dashed in pieces vessels passing through them. According to instructions previously received, they caused a dove to fly through before them, and followed, rowing with all their strength, while Orpheus played on his lyre. The rocks stood firm, and the danger was escaped. The last adventure awaited them at the Island of Aretias. Here they found the Stymphalides, birds which shot their feathers like arrows, and from which the heroes could only protect themselves by a violent clashing of weapons. On their arrival at Colchis King Æetes did not refuse absolutely to deliver the golden fleece, but charged Jason with three dangerous labors, thus hoping to destroy him. Jason was to yoke the two fire-breathing bulls of Hephæstus to a ploughshare of adamant, and to plough with them four acres of land consecrated to Ares (Mars), and never before turned up. He was then to sow in the furrows the remaining serpents' teeth of Cadmus, in the possession of Æetes, and to kill the armed heroes which they produced; at last, to fight with and slay the dragon that guarded the golden fleece. All three labors he was to accomplish in a single day. With the help of Medea, the daughter of Æetes, these tasks were accomplished and the fleece obtained. Jason then fled with Medea, but the fugitives were pursued and on the point of being overtaken when Medea averted the danger by killing her brother Absyrtus, and strewing on the road his mangled limbs. The unhappy father quitted the pursuit to collect the bloody limbs of his son and the fugitives escaped. The return of the Argonauts is variously told, but after many perils they reached Iolcos and gave the fleece to Pelias.

Argonauts of '49, a literary name (the colloquial one being «Forty-niners») applied to the California pioneers. The first discovery of gold was in January 1848, but it was not generally realized till April; from thence till the following winter California itself (recently obtained by the United States from Mexico) was partially depopulated outside the mining camps, even soldiers and sailors deserting in great numbers and rushing to the mines, while executive authority was paralyzed. These local changes of place, however, did not constitute a «voyage for the Golden Fleece» from far distant regions, which is what the term implies. The excitement, spread by official reports and intensified by journalistic inventions, had fully roused the East by winter; from January onward the great sea routes were thronged. By the end of the year the new province (it never was organized as a Territory, entering the Union as a State from a condition of legal nullity or permitted trespass) contained toward 100,000 people. The imperfect State census of 1852 showed 264,435, nearly all Argonauts proper.

Much the greater portion came by sea; the favored route being by the Isthmus of Panama. The passengers landed at Chagres, took boat up that river to Cruces, then crossed over by horse or mule conveyance to Panama, where they took such coasting steamers or sailing craft as came along. The crowds which flocked thither by all sorts of Atlantic vessels far outran the Pacific fleet's capacity, and large numbers had to wait many weary weeks for a passage. At one time 3,000 were collected at Panama, so wild with impatience that several small companies unsuccessfully attempted to make the voyage to San Francisco in the natives' log canoes. An assemblage of several hundred to a thousand was common; and at one time they enlivened the tedium by issuing a newspaper. But a far more terrible foe than ennui had to be faced: the cholera and Panama fever, which carried off great numbers of the emigrants and a quarter of the inhabitants of Panama. Before the excitement had begun, two new steamers, the California and Oregon, were assigned to this route to run monthly. The fare was $300, and the competition for space was so great that double price was sometimes paid. The California reached San Francisco on her first trip 28 Feb. 1849. When she came up the west coast after rounding the Horn to reach Panama, the gold fever had just reached Peru, and 75 Peruvians took passage. This preoccupation of space so enraged the 1,000 or so of waiting Americans that they induced the commandant of the United States forces in California, who was waiting with them, to issue a proclamation ejecting the Peruvians as intending trespassers on United States public lands not yet opened for settlement. As they refused to go, however, no one dared use force. In one case some 300 intending passengers drew lots for the 52 steamer tickets on sale. Many gold-seekers crossed at Nicaragua, at the isthmus of Tehuantepec, or at central Mexico. Many thousands, however, chose the cheaper and unbroken but time-wasting sailing voyage of several months around Cape Horn. The vessels on this route were miscellaneous and often unfit and ill manned; the food was poor and insufficient, and the voyage full of hardship. There was also a large overland emigration across the plains, through the Great Basin and its alkali deserts, and over the Coast Range. This journey, too, was full of suffering from lack of food, lack of water, lost trails, and exhaustion; and sometimes after a summer of endurance to the last gasp, the

pilgrims saw the snows close up the mountain passes before them, and either wintered or died on the eastern flank, or lost themselves trying to penetrate through the snow. This overland body had two strongly distinguishing marks from the immigrants by sea. First, it contained nearly all the families among the Argonauts, as distinguished from the solitary masculine adventurers; and therefore nearly all the women. Second, it was nearly all a Northern and free-labor element — an important point in the struggle to make new States free or slave then going on between the sections.

The characteristics of the Argonauts as a body were these: First, they were mostly men, with a few low-caste women, and their moral sense was not therefore quickened by the presence and needs of family life; though families and reputable women were by no means so utterly absent as the exaggerated myths of the old-timers would make it appear. Second, few intended to remain longer than was needed to acquire a fortune and return East. This did not make their settlement in the least less enduring or desirable; but with the paucity of family life, it prevented them for some time from feeling a proper responsibility for public order and the creation of solid institutions, and spasms of illegal violence were expected to do the work of steady legality. Third, they were from all sections of the country, at a time when North and South were daily becoming hostile races. Though the free-State people were largely in the ascendant, the Southerners were the political leaders and the State was steadily Democratic. Yet the former class had no idea of letting sectional politics rule their general action: home issues were too pressing and national ones too academic; and while California as a free State sympathized with and furnished splendid help to the Union, her politics have never been affected by the issues either of slavery or of reconstruction. Fourth, along with men of character and ability, since prominent as business and professional men, State officials, editors, etc., there were of course great numbers of blacklegs, desperadoes, and refugees from justice. These not only defied all law in their relations with each other, but frequently outraged, plundered, and murdered the native Spanish inhabitants, and required an amount of time and effort to keep them in order, which the decent element — who were in a great majority — were unwilling to give. Hence society again and again seemed on the verge of being dominated wholly by its criminal classes, and the fear of an occasional uprising of the orderly element did not countervail its being only occasional and the chance of escaping it. (See VIGILANCE COMMITTEES.) But the best praise which can be given to the essential soundness of the Argonauts is that in a remarkably short time they rose to the same sense of their responsibilities as older commonwealths, and the California of 1860 was not inferior to any of its companions. See Royce, 'History of California' (1891); H. H. Bancroft, 'History of California,' 4 vols. (1884–90); Shinn, 'Mining Camps' (1885); Bayard Taylor, 'Eldorado' (1850); Burnett, 'Reminiscences of an Old Pioneer' (1880).

Argonne, är'gŭn', a district of France, now contained in the departments of Marne and Ardennes. The wood of Argonne is celebrated for the campaign of Dumouriez against the Prussians in 1792, and was also the scene of several events in the Franco-Prussian war.

Ar'gos, an important city of ancient Greece. The conquest of Argos by the Dorians forms the first really authenticated event in its history. Argos was now a Doric city, though it retained with part of its Achæan population some of its ancient habits, particularly the worship of Hera (Juno). It had also a temple of peculiar sacredness to Apollo. It was long the first Dorian city in Greece, Sparta being the second, and Messene the third. From the time of the ascendency of Sparta, Argos was divided between a democratic and an oligarchic party, the former of which inclined to the Athenian, the latter to the Spartan alliance; but the general spirit of the city tended toward enmity to Sparta. In 362 Argos fought with Thebes against Sparta and Athens. The celebrated Pyrrhus was killed in an invasion of Argos in 272. In 229 Argos joined the Achaian League, to which it continued to adhere till its overthrow by the Romans. The town of Argos is a straggling modern place, with houses mostly surrounded by gardens, and few buildings of importance. The chief relic of the ancient city is the theatre. There is an acropolis, 1,000 feet high, crowned by a ruined castle. Pop. 10,000.

Argostoli, är'gŏs-tō'lę, an important city of the Ionian Islands, the capital of Cephalonia. Its harbor is considered the best in the Ionian Islands, and there are excellent quays. The town is the residence of a Greek bishop. Pop. (1890) 9,241.

Argot, är'gō', a French term denoting the jargon, or peculiar phraseology of a class or profession. It originally referred to the conventional slang of thieves and vagabonds, invented for the purpose of disguise and concealment.

Argout, är'goo', **Antoine Maurice Apollinaire, Count d',** a French statesman and financier: b. in Isère in 1782; d. in 1858. He was governor of the Bank of France, 1834–48.

Arguelles, är'gā'lyas, **Augustin,** a Spanish statesman: b. in Rivadisella in Asturias in 1776; d. in Madrid, 23 March 1844. On the outbreak of the war of independence in 1808 he attached himself to the patriotic party, and, as representative of his native province in the Cortes, gained a high reputation for eloquence (1812–14). On the restoration of Ferdinand VII., Arguelles was arrested, and suffered several years' imprisonment in the galleys till the revolution of 1820 restored him to freedom. On the fall of the Constitution (1823) he fled to England, where he remained till the amnesty of 1832. On his return to Spain, being nominated to the Cortes, he was repeatedly made president and vice-president of the Chamber of Deputies, and always showed himself a moderate but unwavering reformer.

Ar'gument, a term sometimes employed as synonymous with the subject of a discourse, but more frequently appropriated to any kind of method employed for the purpose of confuting or at least silencing an opponent. Logicians have reduced arguments to several distinct heads, of which the only one that can be said to have truth only for its object is the *argumen-*

tum ad judicium, founded on proof and addressed to the judgment. See LOGIC.

Ar'gument, a legal term applied to an address by counsel to the court or jury in which the merits of the client's case are set forth with reference to effect upon the verdict or decision which is to follow. See TRIAL.

Argun, är-goon', a river of northern Asia, an affluent of the Amur, and about 1,100 miles long.

Ar'gus, a personage represented in Greek mythology as having 100 eyes, or as having his whole body covered with eyes, half of these being always awake while the rest were closed in sleep. The jealous Hera made him keeper of the unhappy Io; but Hermes lulled him to sleep with the sound of his flute, and cut off his head. Hera afterward took his eyes to adorn the tail of the peacock. Argus was once considered a desirable name for a watch-dog.

Ar'gus Pheasant. See PHEASANT.

Argyle, är-gīl', **Campbells of**, the designation of a distinguished Scottish family. Among its most noted representatives are: ARCHIBALD, the second Earl, who was killed at the battle of Flodden, 1513. ARCHIBALD, fifth Earl, attached himself to the party of Mary of Guise, and was the means of averting a collision between the reformers and the French troops in 1559. He was commissioner of regency after Mary's abdication, but afterward commanded her troops at the battle of Langside, and died in 1575. ARCHIBALD, eighth Earl and Marquis, b. 1598, was a zealous partisan of the Covenanters, and was created a Marquis by Charles I. It was by his persuasion that Charles II. visited Scotland, and was crowned at Scone in 1651. At the restoration he was committed to the tower, and afterward sent to Scotland, where he was tried for high treason, and beheaded in 1661. ARCHIBALD, ninth Earl, son of the preceding, served the king with great bravery at the battle of Dunbar, and was accordingly excluded from the general pardon by Cromwell in 1654. On the passing of the Test Act in 1681 he refused to take the required oath except with a reservation. For this he was tried and sentenced to death. He, however, escaped to Holland, whence he returned with a view of aiding the Duke of Monmouth. His plan, however, failed, and he was taken and conveyed to Edinburgh, where he was beheaded in 1685. ARCHIBALD, tenth Earl and first Duke, son of the preceding, died in 1703. He took an active part in the revolution of 1688–9, which placed William and Mary on the throne, and was rewarded by several important appointments and the title of Duke. John, second Duke and Duke of Greenwich, son of the above, was born in 1678 and died in 1743. He served under Marlborough at the battles of Ramilies, Oudenarde, and Malplaquet, and assisted at the sieges of Lisle and Ghent. He incurred considerable odium in Scotland for his efforts in promoting the union. In 1715 he fought an indecisive battle with the Earl of Mar's army at Sheriffmuir, near Dunblane, and forced the pretender to quit the kingdom. He was long a supporter of Walpole, but his political career was full of intrigue. He is the Duke of Argyle who appears in Scott's 'Heart of Midlothian.' GEORGE JOHN DOUGLASS CAMPBELL, eighth Duke, Baron Sundridge and Hamilton, was born in 1823 and died 24 April 1900. He early took a part in politics, especially in discussions regarding the Presbyterian Church of Scotland. In 1852 he became lord privy seal under Lord Aberdeen, and again under Lord Palmerston, in 1859; postmaster-general in 1860; secretary for India from 1868 to 1874; again Lord privy seal in 1880, but retired, being unable to agree with his colleagues on their Irish policy. He was the author of 'The Reign of Law' (1866); 'Primeval Man' (1869); 'The Burdens of Belief' (1894); 'Organic Evolution' (1878). JOHN DOUGLAS SUTHERLAND, ninth Duke, eldest son of the preceding, was born in 1845. He married Louise, the fourth daughter of Queen Victoria, in 1871, and as Marquis of Lorne was governor-general of Canada 1878–83. He succeeded to his present title in 1900. He is the author of 'A Trip to the Tropics' (1867); 'Guido and Lita' (1875); 'The Psalms Literally Rendered in Verse' (1877); 'Canadian Pictures' (1885); 'Imperial Federation' (1885).

Argyllshire, är-gīl'shĭr, an important county in the highlands of Scotland, consisting partly of mainland and partly of islands belonging to the Hebrides group. The area is 3,213 square miles, or 2,056,400 acres. The greatest length of mainland is about 115 miles. From the windings of the numerous bays and creeks with which the land is everywhere indented it is supposed to have more than 600 miles of sea-coast. The chief towns are: the capital, Inverary, Campbeltown, Oban, Dunoon, Lochgilphead, and Tobermory. For a long time this county scarcely formed part of the kingdom, being subject to the Macdonalds of the isles, who assumed regal and independent sway over it. The estates, titles, and jurisdiction of the latter, however, subsequently fell to the Campbells, whose present representatives, the Duke of Argyle and the Earl of Breadalbane, are the chief landed proprietors.

The chief articles of export are sheep, cattle, horses, fish, slate, and granite. One of the most important branches of industry is the fishing of herring, cod, and ling, which abound on the coast and around the islands. The principal manufactures are whisky and coarse woolens. A great impulse has been given to the prosperity of the county by the extension of steam navigation. Among the antiquities of Argyllshire are the celebrated monastery of Iona, and the remains of a Cistercian priory in Oronsay. The most noted of its natural curiosities are the basaltic columns and cave of Staffa (q.v.) Pop. (1901) 73,665.

Argy'ria, or **Silver Poisoning.** See TOXICOLOGY.

Argyro-Castro, är'gē-rō-käs'trō (Turkish Ergree-Kastree), a town of Albania, 50 miles northwest of Janina. It is picturesquely situated on an elevated rocky site intersected by deep ravines and overlooked by a dilapidated castle. Turkish snuff is manufactured here.

Argyr'odite (Greek, "like silver"), a mineral first observed at Freiberg, Saxony, and found upon analysis to contain a previously unknown metallic element, to which the name "germanium" has been given. Argyrodite has the formula $4Ag_2S.GeS_2$, and crystallizes in the isometric system. It has a hardness 2.5 and a specific gravity varying from 6.08 to 6.26. It has

a metallic lustre, and fresh fractures show a gray color tinged with red or violet. Its crystals are usually small and it also occurs massive. Large crystals have been found in Bolivia.

Ari Thorgilsson, ä'rẹ-tôr'gẹl-sōn, the father of Icelandic literature: b. in 1067; d. in 1148. He was the first Icelander to use his mother tongue as a literary medium. His 'Islendingabók,' a concise history of Iceland from its settlement (about 870) until 1120 is preserved only in an abstract. Later Icelandic writers modeled their style upon his.

Aria, ä'rẹ-ạ or ā'rĭa, a term in music. See Air.

A'riad'ne, the daughter of Minos, king of Crete, who, having fallen in love with Theseus when engaged in his attempt to destroy the Minotaur, gave him a clue of thread, which served to guide him out of the labyrinth after having slain the monster. Theseus, on leaving the island, took with him Ariadne, but deserted her on the Isle of Naxos.

A'rianism is the name given to the doctrine of the person of Christ advocated by Arius and his followers. It contained nothing essentially new, but it crystallized certain modes and tendencies of thought which had been more or less prevalent in the Church for three or four generations. (See Christology.) The views of Arius and the strict Arian party may be summarized as follows: (1) The Son was created out of nothing, and is therefore *different in essence* from the Father. He is Logos, Wisdom, Son of God, but so only by the *grace* of God and not in and of himself. (2) There was (before time began) when he was not; that is, he is a finite being. (3) He was created before everything else, and through him the universe was created and is administered. (4) The Logos became the soul of the historical Christ, and the human elements in the character of Jesus belonged to the Logos. (5) Although the incarnate Logos is finite and hence is not God, he is to be worshipped, since he is exalted far above all other creatures, and is both Ruler and Redeemer.

The discussions at the Nicene Council revealed the fact that there were three parties present: the strict Arians, the semi-Arians, and the Alexander-Athanasian party. The latter party with the help of Constantine and the western bishops, secured the adoption of a creed (see Creeds) which no strict Arian could subscribe to, since it declared that the Son is *identical in essence* (*homoousian*) with the Father. The semi-Arians, although they maintained that the Son was not *identical in essence*, but of *similar essence* (*homoiousian*) with the Father, were finally constrained to sign the document. Soon after the closing of the council the semi-Arians began to assail the Nicene creed, and finally, through the influence of Eusebius (q.v.), they secured the recall of Arius and his companions and the deposition and banishment of Athanasius. The sons of Constantine continued to favor the semi-Arian party, which included a large majority of the eastern bishops; but the western churches generally adhered to the Nicene creed. But the death of Constantius II. in 361, and the accession of Julian left the Arian party without imperial support, and Athanasius and his followers regained considerable influence in the east. The accession of Valens in 363, however, reversed the governmental policy and led to the fanatical persecution of the Nicenes. But the distracted condition of the Orient, due to the war with Persia, and the demoralized state of many of the bishoprics under Arian leadership, made it relatively easy for Theodosius the Great to espouse and support the Nicene party. A second œcumenical council held at Constantinople in 381 reaffirmed the Nicene creed with slight additions and curtailments, thus completing the victory of Nicara in favor of the full deity of the Son. Arianism was soon suppressed within the empire, but it continued for a long time to prevail among the barbarians. The conversion of Clovis, king of the Franks, to the orthodox faith in 496 was followed by a rapid decline of Arianism among the Teutonic peoples. See Arius.

Edwin Knox Mitchell,
Hartford Theological Seminary.

Ariano, ä'rẹ-ä'nō, an Italian town in the province of Avellino, 44 miles northeast of Naples, in one of the most frequented passes of the Apennines. It is the seat of a bishop, and contains a handsome cathedral. Pop. (1901) 17,650.

Arias, ā'rĭ-ăs, **Montanus Benedictus,** an Oriental scholar: b. Ferexenal, Spain, in 1527; d. there in 1598. He accompanied the Bishop of Segovia to the Council of Trent, and on his return secluded himself in a cloister among the mountains of Andalusia. Philip II. drew him forth from his seclusion to prepare a new edition of the Polyglot Bible, printed at Antwerp by the celebrated printers Plantin. Of his numerous writings the best known is his 'Jewish Antiquities,' attached to the Polyglot, and also published separately.

Arica, a-rē'kạ, a seaport of Chile, 30 miles south of the town of Tacna, with which it is connected by railway. It is still a port of some consequence, but has suffered much from earthquakes. During the war between Chile and Peru it was bombarded by the Chilean forces, and it passed into the possession of Chile in 1883. The chief exports are silver and silver ore, copper, bark, chinchilla skins, and alpaca wool. From this port the silver from the mines of Potosi used to be shipped for Europe. Pop. about 4,000.

Arimathea, a town in Judea and, according to Saint Jerome, not far from Lydda. It is mentioned in the Gospels as the home of Joseph, a member of the Sanhedrin, who had the honor of giving the burial place for the body of the crucified Christ. Joseph of Arimathea is also mentioned in the Arthurian legends as having brought the Holy Grail from Jerusalem.

Ar'icite, a mineral more correctly known as Gismondite (q.v.).

Ar'id Lands. See Deserts.

Ariege, ä'rẹ-āzh', a French department, separated from Spain by the Pyrenees. The arable land is small in quantity, but a considerable number of sheep and cattle are reared. The manufacturing industry is considerable, but lead, copper, etc., are abundant. The chief town is Foix. Area, 1890 square miles; pop. (1901) 210,527.

Ariosto, Ludovico, an Italian poet: b. Reggio 8 Sept. 1474; d. Ferrara 6 June 1533. His father, who was commander of the citadel of Reggio, proposed that he should study law, but, as he showed no indication of being fitted for this profession, he was finally permitted to follow his own inclinations. These led him to the study of literature, especially the classics, and he soon developed so much ability as a poet that, as early as 1495, he wrote several comedies. Two of them were acted about 1512, and they attracted the attention of Cardinal Ippolito d' Este, who sent him as an ambassador to the court of Pope Julius II. In 1517 he offended the cardinal by refusing to accompany him to Hungary, but he immediately entered the service of Alfonso, Duke of Ferrara, by whom he was appointed governor of Garfagnana, a position which he filled successfully for several years. The last years of his life were spent in writing comedies and in completing his principal work, a romantic epic, 'Orlando Furioso,' which has been called "the greatest poem of its kind in any language." His 'Satires' in the Horatian style were not published until after his death.

Ar'isti'des the Just, an Athenian statesman: b. near the middle of the 6th century B.C.; d. about 468 B.C. He was one of the ten generals of the Athenians when they fought against the Persians at Marathon, 490 B.C. According to the usual arrangement the command of the army was held by each of the generals in rotation for one day. But Aristides prevailed on his colleagues each to give up his day to Miltiades; and to this, in a great measure, must be ascribed the victory of the Greeks.

Aristides, Quintilianus, a famous Greek grammarian of the 1st century whose treatise on music is esteemed the most valuable of all ancient writings upon that theme.

Aristip'pus, a disciple of Socrates, and founder of a philosophical school among the Greeks, which was called the Cyrenaic, from his native city Cyrēnē, in Africa; flourished 380 B.C. His moral philosophy differed widely from that of Socrates, and was a science of refined voluptuousness. His fundamental principles were — that all human sensations may be reduced to two, pleasure and pain. Pleasure is a gentle, and pain a violent emotion. All living beings seek the former and avoid the latter. Happiness is nothing but a continued pleasure, composed of separate gratifications.

Aristolochia, a-rĭs'tō-lō-kī'a, a term denoting the type genus of plants of the natural order *Aristolochiaceæ*. The order includes nearly 200 species, mainly shrubs (some climbing), and herbs, natives of warm countries and especially numerous in tropical South America. *A. Sipho* (*macrophylla* of some botanists), the Dutchman's pipe or pipe vine, a native of the southeastern States, is perhaps the best known species grown in America. It is hardy as far north as Detroit. *A. californica*, a silky-haired Californian species with U-shaped flowers, and *A. tomentosa*, a small very hairy species with yellow flowers, found from North Carolina to Missouri and southward, are also grown out of doors to some extent. *A. clematitis*, the common birthwort, a perennial herb, is a European common weed as far north as latitude 50°, and, like *A. rotunda* and *A. longa*, two other herbaceous species, native to southern Europe, was formerly believed to be of service in childbirth, and the latter are still believed to be valuable as emmenagogues.

Ar'istoph'anes, the greatest of the Greek comic dramatists: b. in Athens probably about the year 448 B.C.; d. about 385 B.C. He appeared as a poet in 427 B.C., and having indulged himself in some sarcasms on the powerful demagogue Cleon was accused by the latter of having unlawfully assumed the title of an Athenian citizen. The same accusation was twice renewed against him, but he succeeded in repelling it both times. In 424 he again attacked Cleon in his comedy of 'The Knights,' in which he himself acted the part of the Athenian demagogue, because no actor had the courage to do so. The earliest of his extant plays was 'The Acharnians,' which was brought out in 425. Aristophanes was distinguished among the ancients by the appellation of "The Comedian," as Homer was by that of "The Poet." Of 54 comedies by him only 11 remain; but in order fully to enjoy them, and not to be offended by the extravagances and indecencies with which they are bound, we must be intimately acquainted with ancient customs and opinions. The purity and elegance of his language, which is regarded as a model of the Attic Greek dialect, the skill and care displayed in the plan and execution of his pieces, the wealth of lyric power displayed in his choral odes as well as the overflowing richness of his comic genius, and the various other excellences of his dramas, have gained for Aristophanes the fame of a master. His wit and humor are as inexhaustible as his boldness unrestrained. The Greeks were enchanted with the grace and refinement of his writings; and Plato, the comedian, said the Graces would have chosen his soul for their habitation. On both political and moral grounds he was a strong advocate for ancient discipline, manners, doctrines, and art; hence his sallies against Socrates in 'The Clouds,' and against Euripides in 'The Frogs' and other comedies. The freedom of ancient comedy allowed an unbounded degree of personal satire, and nothing which offered a weak side escaped his ridicule. He feared the Athenian populace so little that he personated them under the figure of a wretched old man called Demos. He incessantly reproached them for their fickleness, their levity, their love of flattery, their foolish credulity, and their readiness to entertain extravagant hopes. Instead of being irritated, the Athenians rewarded him with a crown from the sacred olive-tree, at that time considered an extraordinary mark of distinction. Aristophanes produced, under the name of his eldest son, the 'Cocalus,' his last play. With this what is known as the "middle" comedy began, to be followed afterward by the "new." The names of his extant plays are 'The Acharnians' (425 B.C.); 'The Knights' (424); 'The Clouds' (423); 'The Wasps' (422); 'The Peace' (421); 'The Birds' (414); 'Lysistrata' (411); 'Thesmophoriazusæ,' 'The Frogs' (405); 'Ecclesiasuzæ' (393); 'Plutus' (388). Among editions of his comedies may be mentioned those of Bergk (1867); Blaydes (1886); Holden (1887). English translations of excellence are those by Frere, Mitchell, Rogers, and Kennedy.

Aristophanes of Byzantium, Greek grammarian: b. about 262 B.C.; d. about 185. He was educated at Alexandria, and became the chief librarian of the great Alexandrian library. Ancient critics rank him among the most celebrated critics and grammarians. He deserves great credit for his services to the Greek language and literature. With Aristarchus, he was the principal expert in determining the so-called Alexandrian canon of the classical writers of Greece. He invented a series of critical signs, and greatly improved the notation employed in prosody, including accent, quantity, and breathing. His publications include important critical editions of Greek writers, particularly of Homer — the first of its kind — Hesiod, and the lyricists Alcæus and Pindar. For the plays of the tragic and comic poets he wrote introductions. Little of what he wrote is extant, save fragments in the scholia of the poets, some *argumenta* to the dramatic writers, and a part of the Λέξεις ('Glossary'). Consult Nauck, 'Aristophanis Byzantii Fragmenta' (1848).

Aristophanes (THE ENGLISH), a name frequently applied to Samuel Foote (q.v.), also called "The Modern Aristophanes," because of his abundant good spirits and skill in unsparing ridicule. Garrick was a common object of his wit.

Aristophanes (THE FRENCH), a name sometimes applied to the French dramatist, J. B. P. Molière (q.v.).

Aristophanes' Apology, a poem by Robert Browning (q.v.), published in 1875; the title being in full, 'Aristophanes' Apology; Including a Transcript from Euripides: Being the Last Adventure of Balaustion.' It is a sequel to the poem 'Balaustion's Adventure.' A long work in blank verse, it commemorates the defence made by Aristophanes of his comic art, on learning through Sophocles of the death of Euripides, the tragedian. An extensive article on it may be found in Berdoe's 'Browning Cyclopædia' (1892), with a glossary of terms, etc.

Aristotelianism. Aristotle is the first philosophical writer to make a strict separation of the branches of philosophy. His writings, in terms of their subject matter, fall into the following groups: Logic, Metaphysics, Physics, Ethics, Politics, and the Philosophy of Art. A classification made by Aristotle, but not applied to the arrangement of his writings, is: (1) theoretic philosophy; (2) philosophy of conduct; (3) philosophy of production, that is, of art. The analysis of the problems and subject matter of philosophy and science begins with him. In Plato's writings the various problems are fused together and treated integrally and synthetically in an ethico-metaphysical system.

Logic.— For Aristotle logic is a methodology of science, a propædeutic to the other disciplines. It is not strictly a science, because science has some essence or aspect of reality for its subject matter, while logic is concerned with the forms of knowing. Formal logic was founded by Aristotle and almost completely developed by him. Its chief feature is the doctrine of the syllogism, the process of reaching scientific or apodictic conclusions. The syllogistic process is a deductive process, that is, it derives particular conclusions from general principles or accepted premises. The possibility of deriving such conclusions rests upon the axiomatic principles of contradiction and the excluded middle, that is, two contradictories cannot at the same time and in the same reference be true; and of two contradictory propositions, one must be true and the other false, and a third intermediate proposition is excluded. The logical treatises were grouped together by Aristotle's successors and called the Organon or instrument of science. The several treatises consist of the Categories, the Hermeneutics, the Analytics, and the Topics. The Categories discuss simple terms; the Hermaneutics discuss the combination of terms with a predicate, that is, the judgment or proposition; and the Analytics and Topics discuss the combination of propositions in the syllogism. The syllogistic conclusion is the derivation of one judgment from another by means of a middle term. The notion, judgment and conclusion are the three elements with which formal logic operates. The categories, or general notions under which reality is viewed are enumerated by Aristotle as substance, quantity, quality, relation, place, time, position, possession, action, passion. These ten categories are evidently not derived from any single principle and are neither exhaustive nor mutually exclusive. Aristotle's main interest is in the syllogism; simple terms or notions and the judgment are scantily treated. His treatment of the syllogism is practically exhaustive. Modern logic has supplemented his work by adding to his theory of the categorical conclusion, which was his chief interest, the theory of hypothetical and disjunctive conclusions; further, by adding a fourth figure to his three, and lastly by developing the theory of inductive logic and the method of the sciences. Aristotle regards deductive logic as the only method that can furnish demonstration or apodictic conclusions. Science, however, would not be possible with syllogistic demonstration alone, for if all our premises had to be proven we should be forced into an endless regress. Therefore, science must accept certain fundamental principles as its axiomatic postulates. From these accepted postulates scientific proof proceeds by deduction. In addition to this Aristotle mentions the further method of induction without elaborating it, saying, however, that universal principles are secured by it from particular instances and that it has the advantage over deduction by being nearer to our sense experience and therefore more generally intelligible. On the other hand, he insists that a complete knowledge of particulars is necessary to a completely certain induction and this, owing to the multiplicity of particulars, being rarely possible, induction lacks in its conclusions the cogency of the deductive syllogism.

Metaphysics.— First Philosophy (the term Metaphysics is not used by Aristotle, but is a word applied to the First Philosophy on account of its being placed after the treatises on Physics by the early editor of the works) is the philosophy of first principles as such; second philosophy or physics is the philosophy of these principles applied to concrete phenomena, the phenomena of motion and matter. Aristotle is a disciple of Plato and, like his master, he viewed the world from the standpoint of teleology. The cosmic processes are determined by final causes. He makes more of facts than Plato does, has a much larger mass of empirical data for his constructions and is more catholic in his scientific interests. His metaphysics, however, like

Plato's, is based on high speculative ideas and he explains the world-order by means of these general and ultimate principles, so that he is not a realist in the sense of confining reality merely to particular facts. Like Plato, he sought the essence of phenomena in the concept and law, but unlike Plato he sought it in a concept given in the phenomena as their inner principle of development and not in a transcendent principle. If there is no concept or universal there can be no scientific knowledge. The concept is not, however, an idea isolated from particular things, but as the universal reality it is immanent in particulars (*universalia in re* not *ante rem*), the individual being the only self-existent real. Against Plato's doctrine of ideas Aristotle brings the following criticisms: (1) The Platonists furnish no adequate proof of the existence of ideas as hypostasized entities; (2) The Platonic ideas, because transcendent, cannot explain the phenomenal world, which is left without a principle of motion; (3) The world of ideas is only a reduplication of the world of sense in its generic aspect; (4) The explanation of the relation of the ideal to the sensible world by the terms archetype, pattern, image, etc., is only metaphorical. The universal is real as the formative principle in things, giving to them their generic character, while matter is the principle of individuality. Form and matter are explanatory of genus and individual. In every particular thing, with the exception of God or the Prime Mover (who is pure form), the two principles of form and matter are present; form making the classification of things and scientific knowledge possible, and matter making possible the concreteness of objects. Form and matter are two aspects of individual things and are not really, but only notionally, separable. Everything is both form and substrate, idea and matter, significance and stuff, soul and body, with the single exception of the Supreme Being. Form is the moving principle of development and matter is the passive potentiality. Plastic stuff or matter is moulded after generic patterns. In nature's processes Aristotle calls them energy and potentiality. The real is an explication of a prior potential. The transition of a thing from a condition of potentiality to a condition of actuality is accomplished by some form of motion. Motion in turn (which is of several kinds: spatial, that is, locomotion; qualitative, that is, transmutation of substances; quantitative, that is, growth) implies a moving cause, and any given moving cause an antecedent cause and so the causal regress would be endless, were we not to posit a Prime Mover or uncaused First Cause. The First Cause is the origin and source of all motion and life. As motion is eternal, so the Prime Mover is eternal; it is also immaterial, passionless, and motionless, for the Prime Mover causes motion merely as an ideal toward which matter strives in the processes of nature, analogously to the power of attraction in beauty. The activity of God is pure thought or thought turned upon itself, which theoretic life is for Aristotle the perfect type of life. Between God, as pure form, and matter, as formless stuff,— the extreme cosmic principles, — Aristotle places the world of natural phenomena, which are all composites of the two principles. His doctrine of the Prime Mover is a direct product of his philosophy and is the first attempt to found a theistic theory on a philosophical basis. Aristotle specifies as the four causes operative in nature the formal, final, efficient, and material. But as form contains within itself the principles of efficiency, purpose, and meaning, these four causes are reducible to his dualism of form and matter. As an example of his application of the four causes, a statue presupposes: (1) matter, for example, clay, wood or marble; (2) a form or idea in the artist's mind; (3) an efficient cause, such as the energy applied to tools; (4) a motive or purpose.

Physics.— While the metaphysics treats of being as such, of the unconditioned, of the ultimate principles explanatory of reality, Physics treats of the contingent, the conditioned, and of the quantitative and qualitative relations of things. In the philosophy of nature's phenomena, the concept of motion plays the chief role, effecting the transition of potentiality to actuality and having its ultimate source in the Prime Mover. The whole of growth and development proceeds from one form of being to another form of being, but not from nothing to something, or from non-existence to existence. For Aristotle as for all the Greek philosophers the maxim holds: *ex nihilo nihil fit.* Inert matter is the most formless element in nature and man is the stage in which the highest form manifests itself. Between these nature exhibits a graded scale of development, that is, from the most inorganic to the highest organism. This scale itself is static and not a scale of evolution in the modern sense. The scale of beings is a fixed cosmic hierarchy, not determined by protoplasmic conditions plus environment. The Aristotelian world is a teleological system, the eternal forms working themselves out in plastic and contingent matter with reference to fixed final goals, the whole exhibiting plan, not planless, as Aristotle says, "like a bad tragedy." As the Prime Mover is perfect so the world shows that degree of perfection which is possible with the contingency and imperfection of matter. God is both *in* the world and *outside* of it as the transcendent cause of its order, just as the discipline of an army is in the army and outside of it in the person of the general. The universe is conceived by Aristotle to be spherical in form, not infinite. Its periphery consists of the region of the fixed stars, which revolve in a perfectly circular motion. They do not move freely in space, but are attached to the ethereal body of the outer heaven and move as a rider in a chariot. Their motion is caused immediately by the Prime Mover and being nearest to him, their motion is most perfect. The earth is at the centre of the universe and is fixed. Between the centre and the circumference are the seven planets, including the sun and moon. The motion of these, although concentric with the circumference, is less perfect, deviating from an exact circle. The earth is the region of rectilinear motion. The general presuppositions of motion are space and time. Space is, in Aristotle's conception, strictly speaking, only place, that is, it is the room occupied by body, and time is the measure of motion with reference to earlier and later. Motion being endless, time as the measure of its discrete moments is infinite. Space is finite, for there is no space outside the corporeal world. The elements in the cosmos are fire, earth, air, water, and ether. Of these the first four are sublimary. The celestial spheres consist of pure ether.

Psychology.— Aristotle defines soul as the

"complete realization of a body endowed with the capacity of life." Every body, therefore, that has life, has soul, and psychology in the narrow sense would be a branch of biology. The physical world, according to Aristotle, is divided into two realms, the inorganic and the organic. The characteristic mark of the latter is the possession of life, or "soul." Soul is synonymous with the principle of life, by virtue of which a thing is endowed with the power of self-movement. Life is the universal form of organic activity, feeling and reason are specific forms of the same power. The highest manifestation of psychical activity is rational thought. There are four main forms in which life manifests itself: (1) Nutrition, growth, decay and the power in things to reproduce, each after its kind, whereby the continuity of life is maintained; (2) locomotion; (3) sensation; (4) reason. These various types of life are forms of self-movement. The first form is found in the plant world as well as in the animal world, the last three only in the animal world. Soul as life is found in every part of the body, to which it is related as form to matter. The heart as the anatomical and physiological centre is also the life-centre. The heart, therefore, and not the brain, is the organ of consciousness, for consciousness is one of the forms of life. The processes of knowing or conscious life are developed in these stages: (1) sensation; (2) imagination, the power of using images of absent objects, combined with memory; (3) rational thought. Reason, according to Aristotle, is twofold, creative and passive. All knowledge, in the last analysis, is derived from sense-perception. The mass of sense-perceptions which are held together by memory and stored in the central sense (*sensorium*) are the passive reason, that is, they constitute the matter which the creative reason transforms into conceptual knowledge. The two stand related to each other, therefore, as form to matter, actuality to potentiality.

Ethics.— The ethics of Aristotle consists mainly in a theory of the final end of conduct or the *summum bonum* and an account of the individual virtues. The chief good is happiness (well-being), which is defined as "activity of the reason in accordance with virtue in a complete life." This conception of happiness as consisting in theoretic activity is based on the peculiar function of man. Reason being the differential mark of man, his peculiar good should be discoverable in the activity of reason. Further, the good consists in the realization of the rational self in an ethical life that is complete and not of fragmentary duration, for "one swallow does not make spring." The virtues of an individual are divided into ethical and dianoëtic. The ethical virtues are liberality, temperance, justice, courage, friendship, high-mindedness, gentleness, veracity. The dianoëtic virtues are wisdom, art, insight, cleverness, and such excellencies as attach to the theoretic activity, while the moral virtues are reasonableness expressed in action. Virtue is the power or persistent quality in an individual which enables him to perform his function well. Aristotle otherwise defines it as a "moral habit based on a life of deliberation, and expressed in the observance of a rational mean." The connecting link between ethics and politics is found in the social virtue of friendship.

Politics.— Aristotle gave to politics the position of an independent science, which he based on the study of over 150 actual constitutions. Politics, as the architectonic science, considers the complete good of man, for it is only in the state that man's full realization is attained, and man is by nature a "political animal." Ethics is, therefore, a branch of politics. Although the state is notionally prior to the household and village, it is preceded by them in the order of development. The state is such an aggregation of households and villages as to be self-sufficing. While it comes into being primarily for the sake of life, its growth is determined by the interests of a good and complete life. The individual is not self-sufficient. The end of the state is not power, nor the protection of life, property or industry, but the promotion of noble life in its citizens and of the happiness that springs from such life. The function of the state is educational and moral. One has to keep in mind that the Aristotelian state is a city-state and not an empire. The various forms of good constitutions are: royalty (rule of one), aristocracy (rule of few), polity (rule of the entire people). The corresponding corrupt forms are tyranny, oligarchy and democracy. The best constitution under most actual conditions is the polity, a constitutional democracy, which more than any form of government embodies the principle of the mean and on the average best meets the demands of the greatest number. Under completely ideal conditions monarchy is the best form of government.

Art.—Art has for its function partly the supplementing of nature and partly the imitation of nature. Nature has left man naked and defenseless, but provided him with the "tool of tools," a hand. The useful arts serve the interests of life, imitative and decorative arts serve the ends of noble pleasure and relaxation. The Aristotelian exposition of the philosophy of art is confined almost entirely to the extant fragment of the *Poetics*, in which scarcely more than the theory of tragedy has survived. The function of tragedy is described as catharsis. The conclusion of a tragic representation that is true to the principles of art has the cathartic effect on the spectator of purifying his emotions by the instruments of pity and fear.

History of Aristotelianism.— Aristotelianism was continued in the peripatetic school (the name peripatetic came from Aristotle's method of giving instruction while walking, or from the walks — περίπατοι — in the Lyceum's grounds) down to 529 A.D., when the Emperor Justinian closed all the Athenian schools. During the early Middle Ages it was kept alive by the works of Boethius and the Isagoge of Porphyry. Later by its fusion with the theology of Thomas Aquinas it became practically the offical philosophy of Roman Catholicism, which it still continues to be. The Arabs in Spain were the bearers of Aristotelianism to mediæval Europe, and by 1220 almost all of Aristotle's works had been translated from the Arabic into Latin. A little later, by the efforts of Thomas Aquinas, they were translated from Greek originals, and Aristotle's authority in science became well-nigh absolute. With the rise of Humanism Aristotelianism began to wane, and with the development of modern science and the Cartesian philosophy his influence outside the Catholic Church was to a large extent nullified. Within the

Church, however, during the last quarter of a century, through the efforts of Leo XIII., the influence of Thomism and Aristotelianism has increased.

William A. Hammond,
Professor of Ancient and Mediæval Philosophy, Cornell University.

Aristotle, Greek philosopher, and one of the greatest thinkers and scientific investigators and organizers the world has ever seen.

Life.—Aristotle was born in 384 and died 322 B.C. His birthplace was Stagira (hence he is often called "the Stagirite"), a city on the Thracian peninsula known as Chalcidice, which was at that time a thoroughly Hellenic country, enjoying all the advantages of Greek culture. His father, Nicomachus, was the court physician and friend of the Macedonian king Amyntas. The medical profession is said to have been hereditary in his family, and the scientific and medical atmosphere in which he grew up probably helped to form his mind in those habits of accuracy and exactness for which he is famous. Both parents having died, his education was directed by Proxenus of Atarneus. In 367 B.C., when in his 18th year, Aristotle came to Athens, and became a member of the Academy, the school of Plato (q.v.). Here he remained until the death of Plato, 20 years later. Before this time, he had become renowned for his scholarship and brilliant writings, as well as through his public lectures on rhetoric. Doubtless he had also already developed to some extent his own philosophical views. There seems to be no truth in the charges that were brought against Aristotle by later writers, that he was guilty of ingratitude and active hostility toward his teacher, Plato. As we have seen, he remained a member of the Academy until Plato's death, and in his later writings, although criticising with keen insight certain Platonic doctrines, he speaks of his master with the greatest reverence and affection (cf. Zeller, 'Aristotle and the Earlier Peripatetics,' Vol. I., Chap. I.).

After Plato's death, Aristotle resided for three years at the court of Hermias, ruler of Atarneus, who had been at one time a member of the Academy, marrying there Pythias, the niece, or, as some say, the daughter of the prince. Hermias, however, was treacherously put to death by the Persians, and Aristotle withdrew to Mitylene. Soon after (343) Aristotle was called by Philip of Macedon to undertake the education of his son Alexander, the future conqueror of the world, then a boy of 13 years. Nothing is known regarding the nature of the education which Aristotle gave to his distinguished pupil. The regular instruction of the prince must have ceased three years later when he was made regent by his father and entrusted with military duties. Aristotle remained in the north engaged in scientific work, though probably still retaining some connection with the prince and the Macedonian court. When Alexander set out upon his campaign in Asia, Aristotle went to Athens and founded there his school. Its place of meeting was the Lyceum, a gymnasium attached to the temple of the Lyceian Apollo. He was accustomed to talk to his pupils as he walked to and fro in the gardens of the Lyceum, and from this custom the school became known as the "Peripatetic" (περιπατεῖν, to walk up and down).

Here Aristotle taught and directed the various scientific activities of the school for twelve years (335–323). This school was not merely an institution for imparting instruction. It was also an intimate association of scientific workers, many of them, like Theophrastus (who succeeded Aristotle in the leadership), mature men and ripe scholars. The organization and direction of the investigations as well as the fruitful utilization of materials and synthesis of results were, however, the work of the master. During these years, Aristotle systematized the knowledge of the past, and thus defined the limits and laid the foundations of the sciences of the western nations. But he did more. He carried on investigations and extended the boundaries of knowledge in almost every field. In logic, metaphysics, ethics, and politics, he reached conclusions that are of great and permanent significance for all time. Moreover, in psychology, zoölogy, physics, astronomy, æsthetics, and also in his historical investigations, his work is of the greatest value and importance for all the subsequent developments of these sciences. See Aristotelianism.

After the death of Alexander the Great, the Greek states, with Athens at their head, attempted to free themselves from the Macedonian power. Aristotle's former relation to Alexander, and his friendship for Antipater, the Macedonian governor, made him at once an object of attack. The charge of Atheism was brought against him, as it had formerly been brought against Anaxagoras and Socrates, and he retired to Chalcis in Eubœa, where, in the following year (322), he died.

Writings.—The writings that have come down to us under the name of Aristotle do not by any means represent his complete literary activity. It is nevertheless known that the writings of Aristotle which were lost included: (1) Certain popular works published by Aristotle probably during the time of his connection with the Academy. He himself refers to these as the "exoteric," or popular writings. They were written generally in dialogue form, and modeled, both in subject matter and style, after the works of Plato. (2) Compilations of scientific, historical, and political materials, which were used by Aristotle as data in the preparation of his theoretical works. To this class belongs the 'Constitution of Athens,' fortunately discovered in nearly complete form a few years ago and published in 1891 (English translations, by F. G. Kenyon and E. Poste, both London, 1891).

The works which have survived are those which set forth Aristotle's system in more complete and systematic form, and which were used within the school. The writings which have been known to tradition as those of Aristotle, appear to have come essentially from the edition of Aristotle's works prepared and arranged

by Andronicus of Rhodes about the middle of the 1st century B.C. Of present-day editions of Aristotle's works that of the Berlin Academy (1831–70) may be mentioned. These writings may be classified in the following way:

(a) *Treatises on Logic.*— These were later collected under the title of the 'Organon.' This included the 'Categories,' 'De Interpretatione' (on the parts and kinds of propositions); the 'Analytics,' prior and posterior (consisting of two books each, and developing the doctrine of the syllogism and dealing with scientific methods in general); the 'Topics' (dealing with probable conclusions); and on 'Sophistical Elenchi' (which discusses certain fallacies and the ways of refuting them). The Bohn Library gives an English translation of these works in two volumes by O. F. Owen.

(b) *The 'Rhetoric' and the 'Poetics.'*—The former consists of three books, of which only the first two are regarded as genuine. (English translation by T. Buckley in Bohn Library.) The 'Poetics' has been preserved only in a very incomplete and fragmentary condition. An English translation is given in S. H. Butcher's 'Aristotle's Theory of Poetry and the Fine Arts' (3d ed., 1902).

(c) *The Work 'On the First Philosophy'* — our 'Metaphysics' — which Zeller describes as a torso arbitrarily bound up with a number of other fragments, some genuine, some spurious. (English translation in Bohn Library, by J. H. McMahon, 1889.)

(d) *The Works on Natural Science.*— To this class belong (1) the 'Physics,' with the connected works, 'On the Heavens,' 'On Growth and Decay,' and the 'Meteorology'; and (2) the zoological treatises, 'The History of Animals,' 'On the Parts of Animals,' 'On the Movement of Animals,' and 'On the Generation of Animals'; (3) the psychological writings, including the 'De Anima,' and the smaller treatises known as the 'Parva Naturalia.' Of these works 'The History of Animals' is translated by W. Cresswell in the Bohn Library; 'On the Parts of Animals' by J. Ogle (1882); the 'De Anima' by E. Wallace (1882), and W. A. Hammond (1902). The latter writer under the title 'Aristotle's Psychology' has given also a translation of the 'Parva Naturalia.'

(e) *The Ethics and Politics.*— Aristotle's treatise on ethics is known as the 'Nicomachean Ethics.' It has ten books, of which books V. to VII. are largely made up of additions from the 'Eudemian Ethics.' This latter work is a revision of the Aristotelian ethics by Eudemus, of which only a part has been preserved. The 'Nicomachean Ethics' has often been translated into English. Two of the most recent and best translations are those of F. H. Peters (4th ed. 1891), and J. E. C. Welldon (1892). The 'Politics,' in eight books, was left in an incomplete and fragmentary condition. (English translations by B. Jowett and J. E. C. Welldon.)

J. E. Creighton,
Professor of Philosophy, Cornell University

Aristotle's Lantern, the complex dentary apparatus or oral skeleton and associate soft parts of a sea-urchin (q.v.). The oral skeleton attains its highest development in the *Echinidea* in the Aristotle's lantern of the sea-urchins. The lantern is composed of 20 principal pieces — five teeth, five alveoli, five rotulæ, and five radii — of which the alveoli are again divided into four pieces each, and the radii into two, thus making a total of 40 pieces. This complex apparatus has, beside the inter-alveolar muscles, protractor, oblique, transverse, and retractor muscles. A somewhat similar but less complicated oral skeleton is found in the *Clypcastroida.*

Aristoxenus (Greek, Ἀριστόξενος, *Aristoxenos*), a Greek musician and philosopher of Tarentum, flourished about 350–324 B.C. He was one of the oldest writers, and probably was the greatest of Greek students of the science of music and all its branches. He was a son of Spintharus, who taught him music, having himself studied under Socrates and being possessed of a great knowledge of musical matters. After having received his elementary education he went to study music under Lamprus of Erythræ, and later became a student of philosophy under the Pythagorean Xenophilus of Chalcidice. He afterward went to Athens to study philosophy under Aristotle, and made such rapid strides that, upon the death of Aristotle, he aspired to be his successor and head of the philosophical school; Theophrastus was, however, appointed in his stead. He founded a school of musicians, who were called, after him, Aristoxeneans. The main difference between the systems of the Pythagoreans and the Aristoxeneans lay in the fact that the latter judged of the notes in the diatonic scale exclusively by the ear, while the former determined these mathematically. The only one of his works of any value now extant is a treatise on music, 'The Elements of Harmony.' It was published in three volumes by Meursius in 1616.

Arisugawa, ä're-soo-gä'wa, the title of a noble Japanese family founded in the 17th century and prominent in civil and military affairs. This ancient family was founded by the seventh son of the Mikado Go-Yozei, during his reign from 1587 to 1611. The members of the family did not, however, attain much prominence until January 1868, when Arisugawa Taruhito (b. Kioto 1835; d. 1886), who was the uncle of the mikado, was appointed supreme administrator and commander-in-chief of the army. It was at this time that the duarchy of Mikado and Shogun was abolished and the present form of government established, with the Emperor Mutsuhito as dictator with undivided power. Upon taking office he at once reorganized the army to put down the rebellion in the north, led the imperial troops against the rebels, completely routing them and saving Yeddo from destruction. After this he began military operations in the north, and by his skilful maneuvers soon brought the rebels to terms and the war to a quick conclusion. The next year, in 1869, he returned the sword of justice and the brocade banner, which he had received at the beginning of his campaign against the rebels, to the emperor, thus signifying that he had brought the empire to a state of complete subjugation. In 1875 he became president of the senate, and again in 1877 was placed in command of the forces sent to suppress the Satsuma rebellion, under the leadership of Saigo Takamori. This was a long and severe test of his military ability, and his success, though only won after seven months of hard fighting and the sacrifice of 20,000 soldiers and $50,000,000, showed him to

be a leader born of the highest order of military genius. For this great service the emperor decorated Arisugawa with the Order of the Chrysanthemum and appointed him field-marshal and junior prime minister. His brother, Arisugawa Takehito (b. 1862; d. 1895) traveled in Europe, studying the various military systems, for a time serving as midshipman on H. B. M. ship Iron Duke. Upon his return to Japan he was adopted by the emperor, as he was without heir, and immediately entered the navy as captain, serving throughout the war with China in 1894–5, and dying in the service. His portrait appeared on the first memorial postage stamps ever issued in Japan.

Arita, a-rē'ta, a Japanese town in the western part of Kyushu, famous for its pottery works, dating from the end of the 16th century. The Arita porcelain is highly esteemed.

Arithmetic. This word has been and still is used in two quite distinct senses. It formerly signified merely the science of numbers (see ARITHMETIC, HISTORY OF), and treated such numeral properties as seemed mysterious or peculiar. With the invention of algebra it was often taken to include such portions of that science as referred to the operations and to the number theory. In this sense it is still used in Germany and France to-day, the art of computation being indicated by the names *Rechnung* and *Calcul*. In English, however, the term early came to be applied to both the science of numbers and the art of computation. As the former branch developed the advanced portion was given the distinctive name of Theory of Numbers (q.v.), leaving the name Arithmetic to apply to calculation and its application to business problems. With the recent relegation of the progressions and the roots to algebra, this is the sense in which the word is used in the United States to-day. With this understanding of the term, the leading topics relating to the subject will be considered.

I. Notation and Numeration.—The former, referring to the number symbols, is from the mediæval Latin *notæ*, meaning the numeral characters (see NUMERALS), and the latter, referring to number names, is from *numerus*, number. The distinction between the terms is coming, however, to be less marked than formerly, the word numeration being used for both. The writing and reading of numbers generally refers to positive integers, common fractions (or vulgar fractions, so called to distinguish them from the *fractiones physicæ* or *astronomicæ*, the old sexagesimal fractions still met in angle measure), decimal fractions, compound numbers, and surd numbers. Of these the positive integers are known as natural numbers, the others as artificial numbers. Negative numbers, also belonging to the artificial group, have until recently been excluded from arithmetic. They have, however, so many practical applications that they are beginning to find a place, and in time they will probably be treated in arithmetic so far as necessary for cases involving numbers of opposite nature, like debt and credit, opposed forces, and contrary directions.

The distinctive feature of our present numeral system (see NUMERALS) is its place value. The characters for 5 and 1, written in juxtaposition, indicate addition in the Roman system (VI.); but in the Arab-Hindu notation (51) they indicate 5 *tens* and 1 unit, the 5 having a place value showing that it represents tens. Thus by means of only 10 characters we are able to write numbers of any desired magnitude, and by means of the simple device of decimal fractions we are also able to represent any numbers, however small.

II. Scales.—Because man has a natural counting apparatus in his 10 fingers (see FINGER NOTATION) the world has come to write numbers on a scale of 10, and to give them names based upon a decimal system. We might use other scales, and the duodecimal (scale of 12) would be better on several accounts, although a change is not practicable. There has always been some tendency to use the scale of 12, as is seen in such tables as 12 in. = 1 ft., 12 oz. = 1 lb. troy. The superiority of the duodecimal over the decimal scale lies in the fact that 12 has more exact divisors than 10 has. Therefore the fractions most commonly employed could better be represented on the scale of 12, as is here shown:

	Scale of 10	Scale of 12
½	0.5	0.6
⅓	0.333...	0.4
⅔	0.666...	0.8
¼	0.25	0.3
¾	0.75	0.9
⅛	0.125	0.16
$^1/_{12}$	0.08333...	0.1

In the tables of denominate numbers the tendency formerly was to adopt a varying scale, but at present it is entirely toward a uniform scale, as in the metric system (q.v.):

Uniform scale	Varying scale
10 mills=1 cent	2 pints=1 quart
10 cents=1 dime	8 quarts=1 peck
10 dimes=1 dollar	4 pecks=1 bushel

III. The Fundamental Operations.—These are now commonly considered as four in number, although formerly as many as nine *species*, *atti*, or *passioni*, as they were called, were given. They sometimes included doubling (*duplatio*), because a common method of multiplication was by successive duplations. They also included halving (*mediatio*), this operation being often used in effecting a division. The Rule of Three, Evolution, and Progressions were also commonly included. The fundamental operations may more scientifically be classified as follows, each direct process having two inverses:

Direct	Inverse
Addition: $2+3=5$.	Subtraction: $5-2=3$, $5-3=2$.
Multiplication: $2\times\$3=\$6$.	Division: $\$6\div2=\$3$. $\$6\div\$3=2$.
Involution: $2^3=8$.	Evolution: $2=\sqrt[3]{8}$. Logarithms: $3=\log_2 8$.

Of these the primitive one is addition, multiplication by a positive integer arising when the addends are equal, and involution to a positive integral power arising from multiplication when the factors are equal. Arbitrarily, elementary arithmetic has usually excluded evolution beyond the cube root, and logarithms. It is now tending to relegate cube root to algebra on account of its difficulty and lack of applications. The exclusion of logarithms (q.v.) is due to their relatively late invention, since, if the theory of their computation is ex-

cluded, the subject is simple of presentation and valuable in application.

From the primary operations with natural numbers have been derived operations, designated by the same names and subject to the same laws, involving the artificial numbers. For example, $2 \times \$3 = \$6$ means that \$3 is taken 2 times as an addend, thus: $\$3 + \$3$. But $\frac{2}{3} \times \frac{6}{7}$ cannot mean that $\frac{6}{7}$ is taken as an addend $\frac{2}{3}$ of a time. It means that $\frac{2}{3}$ of $\frac{6}{7}$ is taken, or that $\frac{1}{3}$ of $\frac{6}{7}$ is taken 2 times. It is, however, convenient to broaden the definitions so as to use the same phraseology and symbols as in the case of positive integers. Similar considerations fix a meaning for $-2 \times -3 = +6$, $\sqrt{2} \times \sqrt{3} = \sqrt{6}$, and $\sqrt{-2} \times \sqrt{-3} = -\sqrt{6}$. In certain cases an operation is so difficult that it is more convenient to substitute for it another which gives the same result. This is seen in the case of the division of fractions, where to divide $\frac{2}{9}$ by $\frac{3}{7}$ it is easier to multiply $\frac{2}{9}$ by $\frac{7}{3}$ than to reduce to a common denominator as was formerly done, and then divide, thus: $\frac{2}{9} \div \frac{7}{3} = \frac{2}{9} \div \frac{21}{9} = \frac{2}{21}$.

Of the four common operations, addition is the simplest of comprehension, although not in actual work. In fractions it is usually easier to multiply than to add, as in the case of $\frac{3}{7} \times \frac{14}{27}$ compared with $\frac{3}{7} + \frac{14}{27}$. With integers, both addition and multiplication require the learning of 45 combinations of numbers $(1 + 2,\ 1 + 3,\ \ldots\ 1 \times 2,\ 1 \times 3\ \ldots)$, and the mere memorizing of these facts is as easy in one operation as the other. Subtraction does not require memorizing a table, since it is merely the inverse of addition, and if taught by the "making change" method it uses the addition table, as division uses that of multiplication.

IV. Checks.—An important consideration in all computations is the checking of the work, to be reasonably sure that no error enters. Checks should be applied at every opportunity so that an error may be discovered as soon as it is made, and not vitiate the further work. The most important check in addition is the repeating of the work in the opposite direction, adding downwards if the first addition was upwards. The psychological reason for this is that like stimuli tend to produce like reactions, and if an error has been made it is liable to be made again if the numbers are soon met in the same order. Hence the order is reversed to counteract this tendency. In subtraction the best check is that of adding the subtrahend and remainder. If the remainder was obtained by the "Austrian" or "making change" method, this addition should be performed in the opposite direction as in the check for addition. The best check for multiplication and division is that of "casting out nines." This ancient Oriental method was of especial value when the sandboard form of the abacus (q.v.) was used, since the numbers were so frequently erased as to render a general review of the work impossible. This check has gone out of use in American schools, but it is so simple and valuable that it will probably be revived. The check depends upon two propositions: (1) The excess of 9's in a number (that is, the remainder arising from dividing a number by 9) is the same as the excess in the sum of the digits. In the case of 1247 the sum of the digits is 14, and this divided by 9 gives a remainder of 5. It is customary to cast out the 9's as the digits are added, thus: $7 + 4 = 11$; cast out 9 and 2 is left; $2 + 2 + 1 = 5$, the excess. (2) The excess of 9's in the product equals the excess in the product of the excesses of the factors. In the case here given, the excesses in the factors are 5 and 3, indicated in the right and left angles of the cross. The excess in their product (15) is 6, indicated in the upper angle. The excess in the product, 26187 is 6, indicated in the lower angle. The upper and lower numbers in the cross are the same, showing that the result is probably correct.

$$
\begin{array}{r}
1247 \\
\underline{21} \\

26187
\end{array}
\qquad
\begin{array}{ccc}
 & 6 & \\
3 & \times & 5 \\
 & 6 &
\end{array}
$$

In division, the excess of 9's in the dividend equals the excess in the product of the excesses of the divisor and the quotient, plus that in the remainder. Of course, the check of 9's fails to detect an error involving a multiple of 9. There is a somewhat similar check by casting out 11's, requiring slightly longer time, but in some respects more liable to detect errors.

V. Short Processes.—There are numerous short processes of performing operations, or rather of securing results by substituting simpler operations than those to be performed. Thus to multiply by $12\frac{1}{2}$ it is often easier to annex two zeros (or move the decimal point two places to the right) and divide by 8. In the same way it is easier to multiply by 100 and divide by 4 than to multiply by 25. Such processes depend upon simple number relations of the following kind: $12\frac{1}{2} = \frac{100}{8}$, $25 = \frac{100}{4}$, $33\frac{1}{3} = \frac{100}{3}$, $125 = \frac{1000}{8}$, $75\% = \frac{3}{4}$, $125\% = 1\frac{1}{4}$, $66\frac{2}{3}\% = \frac{2}{3}$. The publication of extensive tables and the perfecting of calculating machines (q.v.) have rendered obsolete most of the short processes involving other kinds of multipliers and divisors.

VI. Compound Numbers.—The four fundamental processes with compound numbers were formerly considered of much importance, since before the introduction of decimal fractions most tables of denominate numbers were on a varying scale. Within a century, however, the metric system (q.v.) and various monetary tables have so decimalized denominate numbers as to take from compound numbers most of their former importance. The only case in which several denominations are commonly used in writing a number to-day is that of English money. In most countries the whole subject is obsolete. The United States still uses the British system except in the monetary table, but it has greatly simplified it, rarely using more than two denominations in the same number. Indeed, within a single generation the metric system has come to be used exclusively in this country in scientific laboratories, and the efforts now being made to secure a large foreign trade will make the system more and more known in commercial and industrial affairs.

VII. Methods of Solving Problems.—There are five general methods of attacking an applied problem, as follows:

(1) We may study typical problems and thus acquire the habit of solving others of the same nature. This is the oldest method, and was practically the only one in use before the 17th century. At present it is coming into renewed prominence in American schools, the type problem being attended (as was not formerly the case) by a large number of exercises.

(2) We may commit to memory rules for

all general classes of problems liable to be met. Historically, this is the second method of attack, and it characterizes the American text-books until nearly the close of the 19th century. The rules were usually inductively inferred from type problems, and pupils committed them to memory. Since in practical life we never depend upon a verbatim rule, this method is rapidly becoming obsolete. In mediæval times there was much effort expended in searching for a general rule that would solve all arithmetical problems. Hence arose the Rule of Three (see ARITHMETIC, HISTORY OF), the Rule of False Position, and other rules of less importance, all of which lost their chief value when algebraic symbolism was invented. Of these general rules only the Rule of Three has survived, being now recognized in the form of Proportion.

(3) We may learn formulas instead of rules. This method was received with some favor for a time, but it has been discarded as a general plan. It has all of the defects of the method of rules, with the added difficulty of an unnecessarily confusing algebraic symbolism.

(4) We may analyze each problem as it arises, simply applying common sense to the solution. When problems are, as they always should be, properly graded to the understanding of the pupils, this plan is better than any of the preceding ones. It establishes a habit of independence and of confidence that is wholly wanting in the older methods.

(5) We may bring to the aid of analysis the representation of the unknown quantity by the familiar algebraic symbol x. This materially simplifies the analysis, and most writers on arithmetic at the present time advocate the plan. The concept of the linear equation with one unknown is a very simple one, and it greatly clarifies the analysis in many cases.

VIII. Nature of the Problems in Arithmetic.—The interests of the ancient and mediæval philosophers were not at all commercial. These men were attracted rather by considerations of the properties of numbers and by puzzles which were imagined to sharpen the wit. The rise of commerce in the later Middle Ages and at the time of the Renaissance, brought into the science a large number of applied problems representing actual business conditions. Principles of conservatism have tended to keep these ancient problems from generation to generation, strengthened by the feeling that mental discipline was as well secured from an obsolete as from a modern problem. It is therefore only recently that the question has arisen, What should be the nature of the problems set for children studying arithmetic? In answer to this question teachers seem to be tending to observe the following principles:

(1) A problem that pretends to set forth a business custom should state the real business conditions of the present. This excludes obsolete business problems, it being the opinion that better mental discipline can be secured from a question relating to genuine commercial matters of the present, than from one relating solely to forgotten customs.

(2) Problems should appeal to the interests and understanding of the children in their respective school years. Arithmetic was formerly taught only to boys who could read and write and who were preparing for business. When the subject found its way into the earlier school years it carried many difficult problems of business down to immature minds. The modern tendency is to replace such problems by others that relate to children's interests. Thus in the primary grades there should be the study of home purchases, of the application of number to the large interests of the country, especially such as appeal to a child's love of nature and of the heroic, and such as relate to the sources of food and clothing. Later, the problems should refer to the more detailed features of the national and world life, to the great industries, trades, and transportation facilities. Finally they should relate to the details of the industrial and commercial life, thus preparing both the boy and the girl for earning a livelihood. In all this there should be an effort to make arithmetic interesting, since when the interest of the pupil is secured the work is prosecuted with more zeal and is attended with better and more permanent results.

(3) In the effort to modernize the problems care must be taken to avoid the extreme of withdrawing from arithmetic all topics involving effort, thus making the subject insipid from its very lack of fibre.

IX. Sequence of Topics.—Formerly arithmetic was taught from a single book, each important topic being met but once. Then came the two-book series, the second book covering the ground of the first, but with more difficult examples, thus forming a spiral of two revolutions. In this way there arose the so-called Spiral Method of treatment, which certain devotees have carried to the extreme of returning to each topic every few days. Between the older topical method and the radical spiral method there has been considerable strife. The latter asserted that the former encouraged forgetfulness because of a lack of review, while the former asserted that the latter gave the pupil no feeling of mastery of any subject. The result has been a compromise, as is seen in all modern American courses. Such important topics as percentage are treated several times, with progressive difficulty, applications like simple interest offering new features on each succeeding occasion. On the other hand, such relatively unimportant chapters as that on longitude and time (semigeographical) are met but once. In the same spirit, the fundamental operations with integers, decimal fractions, and those common fractions often met in business, are frequently reviewed, while compound numbers and fractions involving unusual numerators and denominators are less emphasized. The technicalities of business, including the study of investments, insurance, banking, and exchange, are reserved until the last years of the grammar school, when a child beginning to look forward to being self-supporting is prepared to understand them.

X. Methods.—Various methods have been suggested for presenting arithmetic to children, especially in the primary grades. The serious consideration of this phase of the subject began towards the close of the 18th century, particularly in Germany and Switzerland. With it are connected such names as Trapp, von Busse, Kranckes, Pestalozzi, Tillich, Grube, Tanck, Knilling, and Kaselitz. Each of these writers stood for some principle which he carried to

such an extreme as to render the method generally unusable. Pestalozzi, for example, did great good in his judicious use of objective illustration, but he went to an unwarranted extreme in his emphasis of the unit and in his devotion to abstract work. Tillich suggested a valuable set of number blocks, but his followers went to the extreme of eliminating all other material. Grube wrote a condensed manual for teachers, and systematically treated numbers in concentric circles of progressive difficulty, but he went to several extremes that made the system so absurd that it is now nearly forgotten. On the other hand, every prominent writer of this class has usually suggested some slight improvement which has gradually worked its way into the schools. It has been the universal experience that no advocate of a single method has been able to impress this method on any considerable number of followers. The best teacher has been the one who, being interested in the subject, has imparted that interest to the pupils, who has not been limited to any one set of objects or to any peculiar device, who has made arithmetic modern in its applications, and who has followed the best curricula of the day.

XI. Time Required for the Subject in the Schools.—There has been a gradual diminution in the time allowed to arithmetic in American schools for a number of years past, on account of the demands of more modern studies for a place in the curriculum. As a result there has been decreased attention to the subject, there is less ability on the part of pupils to grapple with problems, and the question has arisen as to the amount of time necessary to secure a reasonable facility in the arithmetical processes. Although the text-books and the teaching have both improved, the curtailment of time and the scattering of the pupils' attention over more subjects have left the results far from satisfactory. It has even been urged that arithmetic be not taught before the third nor after the seventh school year, thus allowing five instead of eight years to the subject. But although it is true that the necessary parts of arithmetic can be covered in five school years, it is equally true that the child has as much delight in his work with numbers in his first school year as he has in the other subjects studied, and quite as much need for this work. It is also true that the number facts are more easily impressed on the memory if the work is begun, as Pestalozzi advised, when a child first enters school. It is therefore better to allow arithmetic to extend throughout the elementary grades, combining with it, if the class is well advanced, some constructive geometry and the first steps in algebra in the eighth school year.

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College, Columbia University, New York.

Arithmetic, History of. Among the ancients there were two distinct sciences now called by the name arithmetic. One had to do with the science of numbers and the other with the art of computation. The former was called, by the Greeks, *arithmetic* (ἀριθμετική), and the latter *logistic* (λογιστική). Logistic was taught to boys going into trade, and among the most ancient peoples it probably involved the use of the abacus (q.v.) and commercial rules relating to rents, loans, exchange, and the settlement of accounts. The nature of the problems being simple, and abacus computation depending largely upon manual training, the instruction in this art seems to have been entirely oral. On this account no ancient work upon the subject is extant, and our knowledge concerning it is derived from such sources as the Babylonian cylinders, early Cretan remains, certain fragments of Egyptian papyri, and the occasional references of literary writers. In the Middle Ages the instruction offered by the Church schools was so meagre from the commercial standpoint that arithmetic schools (*Rechenschulen*) were established, and in these logistic (*Rechnung*) was taught. A number of manuscripts of the 13th, 14th, and 15th centuries are extant showing the nature of the problems then considered necessary, but extant treatises on counter reckoning (see ABACUS) are mostly confined to the first century of printing. Not a few of the problems of importance at that time still survive in the arithmetics of to-day, although substantially obsolete from the commercial standpoint.

The Greek *arithmetic*, or theory of numbers, begins with Pythagoras (q.v.), about 530 B.C., who taught their mystic properties, and to whose school is probably due most of their ancient classification. The fundamental division of numbers seems to have been into odd (ἄρτιοι) and even (περιττοί), the former being masculine, divine, lucky, and the latter feminine, earthly, unlucky. The expression "There is luck in odd numbers," appears in Vergil as "*Numero Deus impare gaudet,*" and probably goes back to the Pythagoreans. The odd numbers were, on account of their geometric representations, also called gnomons (γνώμονες), and it was well known that the sum of the first n of these gnomons, including 1 (which was not generally considered a number until the 17th century), was a square (τετράγωνος). The side (πλευρά) of the square was called by the later writers *radix* (*root*, whence *radical*). It is therefore evident that the Greeks looked upon arithmetic from the standpoint of geometry. Following out this plan, they studied triangular numbers, formed by arranging dots in the form of a triangle, as in the case of 3 (∴), 6, 10, etc., and also pentagonal and other *figurate numbers*, solid as well as plane. Many other classifications were suggested by the Greeks, some of which have remained in our school books until quite recently. Such, for example, included *perfect numbers* (τέλειοι), which are equal to the sum of all possible factors, including 1 (for example, $28 = 1 + 2 + 4 + 7 + 14$), and *amicable numbers* (φίλιοι), each of which equals the sum of the possible factors of the other, including 1 (for example, 220 and 284). Euclid (q.v.) (c. 300 B.C.) emphasized the ancient arithmetic in his books II., V., VII., VIII., IX. and X., although II., V., and X. are nominally geometric. Soon after, Eratosthenes (q.v.) (c. 225 B.C.) made a particular study of primes, and

invented a "sieve" (κόσκινον), which bears his name, for the purpose of sifting out the composite numbers. In the next century Hypsicles (c. 180 B.C.) made a more extensive study of progressions than had before been attempted. It is, however, to Nicomachus (q.v.) (c. 100 A.D.) that we owe the first great treatise on arithmetic (Εἰσαγωγὴ ἀριθμητική), a work which sought to do for that subject what Euclid had done for geometry, and which actually succeeded in turning the attention of the later Greeks from the science of form to the science of number. The next great arithmetician was Diophantus (q.v.), who wrote probably in the 4th century. His arithmetic (Ἀριθμητικά) professes to be in 13 books, but only six (seven in one Vatican MS.) are extant. In the main, however, this treatise relates rather to algebra.

The greatest difficulty of the ancient arithmeticians and calculators lay in the treatment of fractions. This is seen in the oldest mathematical treatise of any note as yet deciphered, a papyrus copied by one Ahmes, an Egyptian scribe of c. 1700 B.C., from an earlier MS., probably dating from c. 2300 B.C. Here all of the fractions, save $\frac{2}{3}$, have 1 as a numerator. For example, $\frac{2}{17}$ was written, in hieratic characters, as $\frac{1}{12}\ \frac{1}{51}\ \frac{1}{68}$, this meaning that the sum of these unit fractions equals $\frac{2}{17}$. The Akhmim papyrus, written more than 3,000 years after the original of the Ahmes work, gives the same treatment of fractions, thus testifying to the difficulty of the subject. While the Greeks and Romans simplified the subject and improved the symbolism, it is to the Hindus and Arabs that we are indebted for our present convenient forms.

The Romans contributed but little to the theory of numbers, although their mercantile spirit doubtless led them to improve the abacus. Their only writer of prominence was Boethius (q.v.), who, early in the 6th century, did much to make the ideas of Nicomachus known in western Europe, and whose treatise was the standard in the Church schools for many centuries.

Of the early Hindu arithmeticians but little is known. There are, however, several works extant that set forth the theory and practice of numbers in the period following the introduction of the zero and the consequent perfecting of the system of place value. (See NUMERALS.) It is in this period that the foundations for our common arithmetical operations were laid. From the Hindus the Arabs of the Bagdad school (c. 800 A.D.) drew their inspiration. The earliest Arab writer to make extensive use of the Hindu numerals, in a text-book on arithmetic, was Al Khowarazmi (q.v.). So prominent was his treatise that his name became a synonym for the Hindu arithmetic, even as Euclid became synonymous with geometry. The early Latin translations, one of which was made by Adelard of Bath (q.v.) (c. 1120 A.D.), went by such names as 'Liber Algoritmi' ('The Book of Al Khowarazmi'), whence comes our word *algorism* (*algorithm*, in Chaucer *augrim*), a name for a long time used to mean the arithmetic of the Hindu numerals.

The Arab arithmetic became known in Christian Europe chiefly through the 'Liber abaci' of Leonardo Fibonacci of Pisa (q.v.), in 1202. In the 13th century the great revival of trade brought into prominence the commercial aspect of the subject, and from this time on the theoretical treatment as exemplified in the works of Nicomachus and Boethius gradually lost ground.

The first printed arithmetic appeared anonymously at Treviso, in Italy, in 1478. In Germany the first one to appear from the press was published at Bamberg in 1482. The commercial supremacy of Italy and Germany was such that their works for the next century were largely mercantile, the arithmetics of the Boethian type being published more often in Paris than elsewhere. It was quite late in the 16th century before France produced many commercial arithmetics, and when these did appear the tendency to unite some of the features of the Boethian arithmetic gave their books considerable influence. The first arithmetic to be printed in England was the prolix theoretical work of Bishop Tonstall (1522), and it was not until about the middle of the century that Recorde (q.v.) began to publish his popular commercial text-book. Owing to the great mercantile activity of Holland between 1575 and 1650, a large number of arithmetics appeared in that country early in the 17th century, and materially influenced the text-books of England. To this creative period of arithmetic is due a large amount of matter once of importance but now quite obsolete. An extended treatment of compound numbers and of certain forms of exchange was more necessary then than now; barter was of great importance; partnership accounts were settled by a process quite different from that of to-day; alligation was of real use in the numerous mints then existing; proportion (usually in the form of the Rule of Three, *Regula de tre*, *Regeldetri*) was much more often used in practice than at present. The first arithmetic to be printed in America was Hodder's popular English work, which was republished in Boston in 1719.

The symbolism of arithmetic amounted to very little before the 19th century, when the symbols invented for algebra (q.v.) between 1550 and 1650 were rather injudiciously adopted in elementary arithmetic. The greatest advance since 1600 has been the invention of decimal fractions, a feature which revolutionized business arithmetic, making percentage simple and common, and rendering tables practicable.

The operations of arithmetic were formerly performed on some kind of abacus (q.v.). At the time of the invention of printing our present forms of addition and subtraction were quite common. There were, however, several methods of multiplication, although our present form was already in favor. The present method of division did not come into general use until the 17th century, although it appears in rare cases in the 15th.

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College, Columbia University, New York.

Arizona (from the former Papago locality of *Arizonac*, or *Arizonaca*, probably meaning "place of small springs," a few miles from the present Nogales, where some celebrated nuggets of silver were discovered in 1736–41. It has no connection with "arid zone," etc.). A Territory of the United States (Western or Pacific group), bounded by Utah and Nevada on the north, New Mexico on the east, Mexico on the south, Nevada, California, and Lower California on the west. It extends from lat. 31° 20′ to 37° N. and from long. 109° 2′ to 114° 35′ W. Area, 113,020 sq. mi. (72,332,800 acres), thus ranking sixth in size among the States and Territories. (See TERRITORIES.)

Topography and Geology.— Topographically the Territory presents two great divisions: a plateau region in the north, made up of approximately horizontal strata, and the mountainous region in the south, consisting of uplifted strata plicated and folded with minerals rocks and intrusive veins. These mountain ranges are numerous and have a general northwest and southeast trend, with intermediate broad valleys often 20 to 30 miles wide. The chief mountain masses are the Castle Dome, Big Horn, Eagletail, Chocolate, Dome Rock, Palomas, Harquahala and Harcuvar in the southwest; the Aquarius and Colorado in the west; the great plateaus rising in what are sometimes called the Northside mountains in the northwest; the San Francisco and Black in the north central; the Carrizo, Lukachukai, and Tunicha in the northeast; the Zuñi, White, Mogollon, and Apache in the east; the Gila, Peloncillo, Pinaleño, Dragoon, Galiuro, Santa Catalina, Huachuca, and Baboquivari in the southeast and south. The isolated volcanic San Francisco mountain, above Flagstaff, is the highest of all, rising in its greatest height to 12,794 feet, and in Humphrey peak to 12,562 feet. The other important peaks in the Territory are Thomas, 11,496 feet; Escudillo, 10,691; Graham, 10,516; Ord, 10,266; and Greens, 10,115, while many others exceed 5,000 feet. To the south the surface falls sharply to low ridges, mostly volcanic; thence by terraced mesas to a great desert plain little above sea-level, cut by gullied stream-beds drawing the occasional rainfall to the broad and shallow Gila. The great northern plateau, or series of plateaus, range in altitude from 5,000 to 7,500 feet; rising from them are numerous mountain spurs, buttes, and the cones of extinct volcanoes, while the Colorado river has cut through 6,000 feet of strata, exposing formations down to Carboniferous and Tertiary marine strata, underlying Tertiary lake sediments and later alluvium; indeed it has been said that every period of the world's history since the dawn of life is represented in the geology of Arizona. The surface of the land as it lies was formed by a huge Eocene uplift, the water action afterward cutting the gorges and shaping the mesas and buttes; another took place in the Miocene, with eruptive volcanoes. Near Holbrook, Navajo County, is a wonderful chalcedony forest (see FOREST, PETRIFIED), with trunks four feet thick cracked into exquisitely colored blocks. Everywhere a feature of the landscape in the northern section are the great isolated mesas of sandstone with scarped and pinnacled sides, often more than a thousand feet in sheer height. Most of the stream courses are dry save in the rainy season, and even then their flow is sometimes swallowed by the sands. The one considerable river is the Colorado (q.v.) which flows generally southwest from Utah for 400 miles through the famous Grand Cañon of Arizona (q.v.), one of the wonders of the world, then turning south, forming the western boundary of the Territory until shortly before it reaches the Gulf of California. Its chief affluent in the Territory is the Gila, which flows entirely across its southern portion; other tributaries are the Virgin, which crosses the extreme northwest corner; the Colorado Chiquito or Little Colorado in the north, and Bill Williams fork in the west. Important tributaries of the Gila are the Salado, or Salt, and the Verde from the north, and the San Pedro from the south.

Climate.—Arizona is entirely within the arid region, but owing to the difference in altitude of the northern and southern portions there is a wide range in temperature, as likewise in precipation between the two sections. The average annual precipitation at Flagstaff from 1859 to 1902 was 24.65 inches, that of Yuma 2.84 inches; while the mean temperature is 45° in the north and 69° in the south. The sandy plains of the southwestern part are the hottest region north of the Isthmus of Panama, 120° in the shade being frequent in summer; but even in this lower area, owing to the dryness of the atmosphere, the heat is not very oppressive in summer, while the winter climate is usually delightful. Heavy snows occur in the mountainous country of the north, and sharp frosts are frequent even in the Salado and Gila valleys; but nowhere are the mountains perpetually snow-capped. In recent years Arizona has become a popular resort for those suffering from pulmonary tuberculosis and catarrhal ailments.

Minerals and Mines.— Arizona is rich in minerals and its mining industry is of prime importance. In 1901 it was third among the States and Territories in copper production, 130,778,611 lbs. having been mined; it was also fifth in silver (2,812,400 fine ozs., commercial value $1,687,440), and sixth in gold (197,515 fine ozs., commercial value $4,083,000). Of lead 4,045 short tons were mined, and the industry is steadily increasing. The value of clay products was $92,986. There are also deposits of coal (as yet but little worked), fluorspar, mica, molybdenum, nickel ores, limestone, marble, granite, sandstone in limitless quantities, chalcedony, tungsten, turquoise, vanadium, garnet (pyrope), and other minerals, and there are numerous hot and mineral springs.

Soil, Agriculture, Forestry.—Of the 72,332,800 acres in the Territory, only 5,200,000 acres are privately owned (the remainder being either public or reservation lands), and of this area only 254,521 acres are actually cultivated. The valley lands, however, are marvelously fertile, experiment demonstrating that in the southern part, under favorable conditions, the yield per acre is 2,150 lbs. for wheat, 4,000 to 5,000 lbs. for potatoes, 12,300 lbs. for tomatoes, 5,000 lbs. for strawberries, 27,000 lbs. for melons, and 1,735 lbs. for corn. Lack of water has been more or less a hindrance to the development of

the agricultural sections, but with the construction of storage reservoirs, recently undertaken by the Government, it is estimated that a total of 10,000,000 acres, or 40 times the present area under cultivation, will be reclaimed. The staple crops are alfalfa, barley, wheat, sorghum, kaffir corn, root crops, sugar beets, green vegetables and small fruits of every variety, apricots, grapes, oranges, lemons, figs, almonds, olives, etc. Experiments in the cultivation of Egyptian cotton are also being made, and it is expected that vast tracts of alkali lands in the south, hitherto believed to be waste, can be utilized for date-culture. In 1899 honey and wax valued at $67,489 were produced.

The mountains and mesas of the northern part are generally covered with nutritious grasses, forming excellent pasturage for cattle and sheep, while irrigated pastures in the south afford means of fattening for market. In 1900 there were 742,635 neat cattle, 924,761 sheep, and 125,063 horses. In 1903 there were slaughtered, for home consumption, 41,803 cattle, while 78,846 were exported. In the same year 250,000 sheep (valued at $2.50 each) were sold. The wool clip aggregated 3,500,000 lbs., valued at 13c. Ostrich farming has become a profitable industry; there are about 1,000 birds, some of which yield a pound of feathers every eight months, the maximum market value being $125 per pound.

The southern plains and parts of the north have a dress of sagebrush, greasewood, yucca, cactus, and other desert growths. Cottonwoods line almost every stream. Mesquite, the giant cactus or saguaro, paloverde, ironwood, Jerusalem thorn, and other trees are indigenous to the southern plains, and vast mountain areas throughout the Territory are covered with pine, cedar, juniper, and other valuable timber. An important lumbering industry has been developed in the vicinity of the San Francisco mountains, but vast tracts of timber in this and other sections have been set aside by the Government at the San Francisco, Black Mesa, Prescott, Santa Rita, Santa Catalina, Mount Graham, Chiricahua, and Grand Cañon forest reserves.

Manufactures and Commerce.—These are both in their infancy, the chief manufactures consisting of smelting and mining ($17,286,517 in 1899), lumber, etc., and carshop work. The value of imports (port of Nogales) in 1903 was $8,469,899; of exports, $4,534,388, a large part being free of duty. Duty collected, $123,805. Internal revenue collected, $45,052.

Railroads, Post-Offices, Periodicals.— In 1903 there were 1,766 miles of steam road, against 1,094 in 1890 and 349 in 1880. The principal lines are the Santa Fé Pacific (393 mi.) across the northern and the Southern Pacific (383 mi.) across the southern portion. At the close of 1903 there were 248 post-offices and 53 periodicals (16 daily, 35 weekly, and 2 monthly).

Finances.—Assessed valuation in 1903, $43,-088,004 (distributed by counties as below); in 1897, $30,613,703. Public debt, net, $1,064,593. Average tax, $1.05 per $100. In the same year there were 11 national banks (capital, $602,500; surplus, $257,631; outstanding circulation, $292,-600; deposits, $3,730,784), and 22 Territorial banks (capital, $773,310; surplus, $301,195; deposits, $4,750,569). There are six building associations with loans of $731,817 on real estate.

Education.— The Territory has a good public school system and is energetic in extending its facilities to its children despite the scattered population. Education is compulsory. The school population in 1903 (6–21 years) was 25,951; enrollment, 20,008; daily attendance, 47 per cent. School libraries contain 15,366 volumes; value of buildings and furniture, $727,-182; teachers employed, 115 men (average salary, $80.33), 359 women (average salary, $67.53). In teachers' salaries Arizona is exceeded only by California and Nevada. Cost of maintenance, 1885, $138,164; in 1903, $415,243. There is a Territorial university at Tucson, normal schools at Tempe and Flagstaff, and high schools at Phoenix, Prescott, and Mesa. There are also numerous private schools and 22 sectarian schools (see below). The Government maintains boarding and day schools for Indians among the various tribes, as well as at Phoenix, Tucson, and Rice Station. These had a total enrollment of 3,195, with 488 teachers and other employes, the cost exceeding $286,000 in 1901.

Religions.— Owing to the large number of persons of Spanish descent and to the activity of the early Jesuit and Franciscan missionaries, the population is largely Roman Catholic. Following are the statistics:

Denomination	Churches	Ministers	Members	Sunday schools	Other schools	Property
Catholic	31*	23	27,000	26	15	$249,400
Mormon	34	146†	6,264	44	4	111,724
Methodist	21	21	1,170	27	....	128,000
Presbyterian	23‡	20	2,112	25	3	126,000
Episcopalian	5	10	1,680	9	....	....
Methodist (Southern)	11	10	757	13	....	42,200

Disciples of Christ	5	2	300	4	....	8,000
Others	13	18	567	14	....	15,550

* Including cathedral at Tucson. There is also an academy, hospital, and sanitarium at Tucson.
† Returns incomplete.
‡ Also five missions.
** Among Apache Indians only.

Charitable, Penal.— The Territory maintains an asylum for the insane near Phoenix, a penitentiary at Yuma, and an industrial school for juvenile offenders at Benson.

Population and Divisions.—The first separate census was taken in 1870, giving, exclusive of Indians, 9,658; in 1880, 40,440; in 1890, 59,620 (excluding tribal Indians but including 1,326 others); in 1900, total, 122,931 (71,795 males, 51,136 females, 98,698 native born, 24,233 foreign born, 26,480 Indians, 1,848 negroes, 1,419 Chinese, 281 Japanese). The principal Indian tribes are: Navaho, about 16,000; Papago, 3,900; Pima, 4,400; San Carlos Apache, 2,542; White Mountain Apache, 1,952; other Apache, 600; Mohave, 2,635; Hopi, 1,841; Walapai, 573; Maricopa, 350; Chemehuevi, 250; Havasupai, 243. There are

13 counties in the Territory, as follows, with their county seats, population, etc.:

County	Area sq. mi.	Population 1900	Assessed valuation 1903	County seat	Population 1900
Apache....	10,736	8,297	[illegible]	St. Johns..	.....

* Area included in that of Gila, Graham, and Navajo counties.

In addition to the towns above named, Jerome, in Yavapai county, is a flourishing mining settlement of 2,861 inhabitants.

History.— The first white men to enter Arizona were probably Juan de la Asuncion and Pedro Nadal, two friars of whom little is known, who penetrated the region in 1538. Fray Marcos of Niza and his negro companion Estevanico, in 1539, journeyed from Mexico to the sources of the Rio San Pedro, thence across the southeastern part of the present Territory to the Province of Cibola. (See NEW MEXICO.) In the following year Niza served as guide to Francisco Vasquez Coronado, who, with a considerable force, visited Cibola and sent two small expeditions which discovered the Hopi villages (called Tusayan) and the Grand Cañon of the Colorado. Meanwhile other parties went from the settlement which Coronado established on the Rio Sonora, northwestern Mexico, explored the region, later known as the Papagueria (from the Papago Indians), to the mouth of the Colorado, where letters had been buried by Hernando de Alarcon who commanded a joint expedition by sea and went up the Colorado for 85 leagues. Antonio de Espejo visited the Hopi villages in the northeastern part in 1583, as did Juan de Oñate, the first governor and colonizer of New Mexico, in 1598, the latter also passing entirely across the Territory to the mouth of the Colorado and back in 1604–5. The first missions were established among the Hopis by Franciscans in the summer of 1629, which, barring the killing of some of the missionaries by the Indians, were successfully continued until Aug. 1680, when, in a general uprising of the Pueblos, the missionaries were murdered and little effort made thenceforth to introduce Christianity. From 1687 the Jesuits, particularly Padre Eusebio Kino, made various journeys into southern Arizona, establishing the missions of San Xavier del Bac in 1699 or 1700, and that of Guevavi in 1732. The present church of San Xavier was begun about 1783 and finished in 1797. In 1752 a presidio was established at Tubac, but in 1776 it was removed to a rancheria of about 80 families of Pima, Papago, and Sobaipuri Indians, known as San Agustin de Tucson (the present Tucson) a few miles northward, at which a few Spaniards may also have settled after 1763. The missions and their *visitas* lead a precarious existence after 1750–3, during which years the Pimas were at war against the Spaniards, killing several priests and plundering the missions, including that of San Xavier. The Jesuits were expelled in 1767 and were followed by Franciscans, who rehabilitated the mission settlements and conducted explorations in unknown or forgotten regions. For many years before and after, the Apache tribes were at almost constant war with the more sedentary Indians of southern Arizona, raiding their settlements, killing the men and carrying off the women; nor did the white settlements fare much better, notwithstanding the presence of the presidios. At the time of the conquest of New Mexico in 1846 by Gen. S. W. Kearny, Arizona formed a part of that territory. By the treaty of Guadalupe Hidalgo in 1848 the section north of the Gila was ceded by Mexico to the United States, while that south of the river was obtained through the Gadsden Purchase (q.v.), approved in 1854. Raids continued, various military expeditions were conducted and outposts established, and rich mineral deposits were discovered during the next few years. By act of Congress approved Feb. 24, 1863, Arizona was erected into a separate Territory, and on Dec. 29 it was formally organized at Navaho Springs. The withdrawal of troops from the frontier at the beginning of the Civil War left the country practically at the mercy of Apaches, who continued their depredations; mines were abandoned and settlements deserted, but with the re-establishment of the military posts the development of the Territory was renewed and has since continued. Strenuous efforts have been made for several years toward the admission of Arizona as a state, but thus far without success.

Throughout Arizona are the remains of pueblos and cliff and cave dwellings which were occupied in prehistoric times by the ancestors of the present Pueblo Indians or allied tribes. Noteworthy among the pueblo ruins is the famous Casa Grande in the Gila Valley, near Florence, which was in much its present condition when Father Kino said mass within its walls in 1694. In the northeast, especially in the Cañon de Chelly, are numerous cliff dwellings, remarkably well preserved.

F. W. HODGE,
Smithsonian Institution, Washington, D. C.

Ar'izo'na, University of, a co-educational institution in Tucson, established by act of legislature in 1885, but not opened till 1891. In 1901 its grounds and buildings were valued at $160,000; its library contained 6,000 volumes and its income from the United States government and the Territorial government was $55,000.

Ark, (1) the vessel in which Noah and his family were preserved during the deluge; (2) a term applied to a chest for the safe keeping of valuables.

The Ark of the Covenant, in the Jewish synagogue, was the chest or vessel in which the tables of the law were preserved. This was 3 feet 9 inches in length, 2 feet 3 inches in breadth, and the same in height. It was made of shittim wood, overlaid within and without with gold.

Arkansas, är'kăn-sâ, "The Bear State," a south-central State of the United States (No. 12 in order of admission); bounded north by Missouri, south by Louisiana, east by Mississippi River, west by Indian Territory, southwest by Texas; a block 3° 30′ north to south, about 250 miles land measure, breadth 175 to 275 miles; area 53,850 miles (No. 23 in United States), 805 water; pop. 1,311,564 (No. 18 in United States), or 24.7 to square mile (No. 29 in density). White, 944,580; colored, 366,984.

Topography.— The eastern side is the Mississippi alluvium, swamps, "lakes," and bayous, overflowed by the rises of the great river despite a vast system of levees or dikes; in the centre it slopes west and south to the rolling uplands and the many east-and-west divisions of the Ozark Mountains (q.v.) — a broken range of low hills with some peaks as high as 3,200 feet, as, for instance, Magazine Mountain, in Logan County. This and other mountains, including the Ouachita Hills, are in the southern part of the State. The most extensive range is that known as the Boston Mountains, in the northwestern part of the State. The upper mountainous, forest, and mineral lands may be separated from the northeast corner of the State to Little Rock, thence south 100 miles, thence to the southwest corner of the State. East of this line the country is hilly, thickly covered with pines, oaks, and other trees until the alluvial soil is reached, extending from the Mississippi westward from 40 to 50 miles in width.

River Systems.— The State is evenly divided by its great name-river (q.v.). Just above its mouth and connected with it by a bayou through the bottoms, the White River, 800 miles long, also enters the Mississippi; rising in northwest Arkansas, it flows through southern Missouri and returns to its own State, receiving at Jacksonport the Black of 400 miles, and near Clarendon the Cache. Farther north the St. Francis of 450 miles comes from Missouri, winds through the delta plains for a long distance nearly parallel to the Mississippi, and enters it just above Helena; the space between them is a mass of cypress swamps and bayous. The southern half is drained by the Ouachita of 500 miles, feeding the Red in Louisiana, and in the extreme southwest by a bend of the Red.

Climate and Sanitary Conditions.— The eastern river bottoms are hot and malarious; but the rest of the State is unsurpassed for healthfulness, and the Ozarks are a noted sanatorium for lung diseases. Mean winter temperature about 38.5; summer, 80. Mean rainfall, in the centre, 50 to 60 inches; in the extreme west, 46.5 inches. The drouths of the farther West and the severe northers of Texas are alike unknown.

Geology, Minerals, and Mining.— The Ozarks are the western extension of the Appalachian system, formed at the same time by the same forces: their basis is Palæozoic,— Lower Silurian in the north, Sub-Carboniferous on the south,— with a patch of Cretaceous in southwest. The southern portion of the State, a part of the great Atlantic belt of coastal plain, lies upon a foundation of Tertiary, overlaid with Quaternary sands and clays. The former make the State one of remarkable richness in mineral wealth. The Ouachitas furnish the silicious novaculite, whence are made the famous "Arkansas" or "Ouachita" oilstones, the finest for sharpening tools in the world; quarried in Hot Springs, Garland, and adjoining counties since 1840; the coarser grades of which and quartzites supply common whetstones, grindstones, burr millstones, etc. They also contain bauxite, a granular clay-ore now the principal source of aluminum, used also for alum and crucibles; building, porcelain, and fireclays. In the northwest are quarried limestone for lime, quartz sand for glass, building sandstone, granite, and slate; and a valuable pink marble called "St. Clair limestone." In the north centre around Batesville, manganese ore is mined for eastern steel works. There is a rapidly increasing production of semi-anthracite coal, which, almost neglected prior to 1885, had risen to $1,687,000 in 1900; lignite has been found, and petroleum, and natural gas. Phosphates, mineral ochres, and salt are found. There are large deposits of marble of many colors in the north part of the State. A railway will soon make these, as well as zinc extracted from valuable and numerous mines in the same section, extensive articles of commerce. There are also in the southern portion of the State large deposits of asphalt, graphite, and inexhaustible deposits of that species of chalk from which Portland cement is made, which is now manufactured on an extensive scale. Zinc ore is an article of some export, and galena, gold, copper, and nickel exist in some quantity, as well as limonite iron ore and salt. More valuable at present are the mineral springs, of which those at Hot Springs have developed a celebrated sanatorium and town.

Soils, Agriculture, and Forests.— Agriculturally the most valuable soil is found in the river bottom-lands, and as the surface rises from these the soil becomes less productive. There are large submerged tracts that only require proper drainage to make them valuable to the farmer.

The extreme fertility of the soil in most parts renders agriculture highly profitable. A raw, sparsely settled State at the time of the war, with less than a third its present population, and that mainly along the great navigable streams, most of it had no old industrial system to be wrecked and remade, but was virgin soil; hence it recovered much faster than other southern States, and when railroads opened it up, the new free-labor system developed it with few obstacles, and the improved farm land has increased from about one twentieth to about one fifth of the entire area, or from some 1,700,000 to close on 7,000,000 acres, one eighth of it in the last decade; two fifths of the State is in farms and half of their acreage improved. It has been a growth almost wholly in small farms; from an average in 1860 of nearly 250 acres, it has sunk in 1900 to 93. A part of this is no doubt due to the small patches rented by the negroes, whose farms average only half the size of the whites, and who comprise one fourth of the farmers.

The northwestern Ozark region has a thin, sandy soil, poor relatively to the rest, which range through the clays and loams of the limestone uplands, the sandy loam of the western Arkansas valley, and the clay and sand of the eastern valley, to the deep black soil of the bottoms, the famous buckshot soil (the incredibly fertile cotton land), and the sticky red "gumbo"

clay of the Red River valley. Yet the first-named section is a superb fruit district, two northwestern counties raising in 1899 1,173,642 of the total 2,811,182 bushels of apples (an almost fourfold increase in the decade), and 3,500,-000 of the 44,000,000 bushels of corn, and two others (one the same) more than half the 12,667,-740 quarts of strawberries. Of the other fruit crops for which the State is becoming famous, the peach crop of 333,642 bushels was raised in the southwest, over one sixth in one county just below the Ouachitas; the same counties chiefly grew the plums, prunes, and grapes, the latter 3,621,000 pounds. Dried and canned fruits amounted to 2,045,910 pounds. Potatoes and sweet potatoes are grown all over the State, but about one fourth came from three counties in the western Arkansas valley. But of course the chief crop is cotton, grown mainly in the south, and of which the crop was 705,928 bales in 1899, and 819,000 in 1900, making the State No. 5 in the United States. Hay and forage play a considerable part; these imply animals, and naturally horses, asses, and mules, for farm work, have multiplied rapidly with the farms; swine also have increased, but neat cattle, milch cows, and sheep have fallen off. Sorghum, though still a considerable crop, has diminished two fifths in the decade. An important industry is rose-culture for perfume, and flowers for seed.

The forested area of the State is three fourths its entire surface — more than 40,000 of its 53,850 square miles, and of a vast variety of hard and soft woods: dense tracts of pine, white and other oaks, hickory, black walnut, hornbeam, locust, pecan, ash, elm, willow, papaw, etc. The St. Francis valley, once a continuous swamp, has been reclaimed and is covered with a heavy growth of cypress, gum, oak, hickory, and sycamore. In the Arkansas valley are red cedar, cottonwood, maple, and various oaks. In all forest products the State has a great industrial future: the value of raw and manufactured forest products in 1900 was about $28,700,000.

Manufactures.— Though this branch of industry is relatively small in Arkansas as yet, its rapid increase,— more than doubling in the decade, from $17,275,192 in 1890 to $37,006,409 in 1900,— and the great forest and mineral basis for it, foreshow a great future. Naturally, over two thirds of it was of wood products; $23,959,-983 in lumber and timber, $2,266,522 in planing-mill stuff, sash-and-blind work, wheel parts, staves, shingles, cedar posts, etc. These were but $8,943,052 and $1,761,932 in 1890. Next to this is the group of cotton industries,— ginning, and making cottonseed oil and cake; the latter produced a value of $2,874,864, against $1,881,-668 in 1890, the former of $1,261,097, though in 1890 only $153,226. Flouring and grist-mill products were $3,708,709, against $2,498,168 in 1890; steam-car construction and repair-shop work, $2,095,447, against $1,299,558. Brick and tile formed another important item. There were altogether 4,794 establishments, employing 28,-150 persons, paying $9,937,387 in wages, and having an output of $45,197,731. The internal revenue collections on taxable manufactures now amount to about $300,000 per annum.

Commerce and Navigation.— The immense extent of its internal waterways, in which it exceeds every other State, compensates Arkansas for lack of a seaboard. The Mississippi is equal to one, however, giving it deep-water communication with the ocean and with the other States of the valley. The Arkansas is navigable its entire course in the State, some 400 miles; the White for 250 miles or so to Jacksonport; the Ouachita and the Red rivers also afford navigation. The real port of Arkansas is New Orleans, and its exports are lumber and cotton.

Railroads and Street Railways.— The slender population of Arkansas and its concentration along the rivers made railways long unnecessary and undesired, and the first one was under construction when the Civil War broke out, with only 38 miles built; in 1870 there were but 256, in 1880 859. The next decade was its real creation as a serious system, and in 1890 it had risen to 2,203.44; slackening for a few years,— 2,439.20 in 1895,— it was 3,082.27 in 1899, and in the next two years 158 more were built, making 3,240.33 in 1901. There are 39 lines in the State, or one to every 16 square miles and 310 people. The rates are controlled by a State railroad commission.

There are five lines of street railway operating 200 miles of track.

Banks.— In 1902 there were seven national banks in Arkansas, with $1,070,000 capital, $336,-000 outstanding circulation, $3,108,000 deposits; $1,003,000 reserve; 39 State banks with $1,243,000 capital, $6,604,000 assets, and $4,464,000 deposits. There is one clearing-house in the State at Little Rock; exchanges in 1901, $34,808,284.

Finances.— The assessed valuation in 1901 was $127,062,903; in 1897, $117,873,253. Annual tax rate, 1.19 mills. Recognized public debt, $1,271,000 at 3 per cent, of which $1,113,000 is permanent school fund, not properly an indebtedness as it can never be paid; unrecognized, $8,-706,773. In 1900 a twenty years' dispute with the United States over its holding of Arkansas bonds, to which the State claimed an offset of damages by failure of the United States to patent 273,000 acres of swamp land to it, was settled by paying to the United States $160,000 and guaranteeing titles to settlers.

Education.— The interest on the permanent school fund (see preceding paragraph), a 2-mill State school tax, and other revenues, amounted in 1900 to about $500,000, the district taxes to $805,000, and the poll tax to $163,000; total, toward $1,500,000, of which only $1,369,000 was expended. There are upwards of 5,000 schools, with over 7,000 teachers, three fifths males, the largest percentage in the United States. But the support is inadequate, the terms average only 70 days yearly,— among the lowest in the country,— and there is no general school superintendence, each locality managing its own and the quality fluctuating with its wealth and public spirit. The almost wholly rural character of the population, here as everywhere, makes the school problem difficult from the dispersion of the pupils. From all these causes, in 1900, of 319,742 white children from 5 to 17, only 185,-490 attended school even for the short terms; and of 123,242 colored children, only 50,386. Yet Arkansas has 10 other States below it in illiteracy. There are 48 public high schools and 24 private secondary schools, besides 7 private normal schools (there are no State ones), and 9 universities and colleges, some co-educational, as follows: Arkansas College, Presby-

terian (1872); Arkansas Industrial University, n.-s. (1872); Philander Smith College, Methodist (1877); Hendrix College, Southern Methodist (1884); Ouachita College, Baptist (1886); Arkadelphia College, Methodist (1890), Arkansas Cumberland College, Presbyterian (1891); Mountain Home College, Baptist (1893); and Central Baptist College for Women, at Conway.

Churches.— The Methodist, Roman Catholic, Episcopalian, Presbyterian, and Baptist are the leading church bodies in Arkansas, as in most other southern States.

Charitable and Penal Institutions.— The only ones of the first class are a lunatic asylum and a deaf-mute school; of the latter, a penitentiary in Pulaski County. There is no reform school for juvenile offenders, who are confined with the older criminals.

Post-offices and Periodicals.— There were 1,859 post-offices of all grades in 1900, and 259 periodicals, 21 daily, 212 weekly.

State Government.— The Constitution is of 1874, amended 1893. Suffrage requires a year in the State and payment of poll tax. Office-holding and being witness in court require belief in God. The governor, State officers, and State representatives hold for two years. The governor has $3,500 salary; his veto is overruled by a majority in each House; if he dies within a year from election a fresh one is held, if later the president of the Senate fills out his term. The legislature meets biennially, session limited to 60 days,— but a two thirds vote of each House may extend it, and the governor may call a special session; the representatives must be at least one from each county, and not exceed 100; the Senate has 30 to 35 members (at present 32), four-year terms; both receive $6 a day and mileage. The Supreme Court has five members elected for eight years; there are circuit courts with judges elected for four years; and the usual county and probate courts. The legislature has power to establish new ones or extend the jurisdiction of old.

State Militia.— There are 1,900, 1,600 being infantry. No county may have over four companies.

Representatives in Congress.— There are seven, under the apportionment of the census of 1900, previously six.

Politics.— The State is overwhelmingly Democratic.

Population and Divisions.— At the first census, of 1820, Arkansas had 14,273 people; 1830, 30,388; 1840, 97,574; 1850, 209,897; 1860, 435,450; 1870, 484,471; 1880, 802,525; 1890, 1,128,179; 1900, 1,311,564. The colored population of 366,984 has increased 75 per cent since 1880, against about 60 per cent for the white. The foreign population is inconsiderable. Only 6.9 per cent of the people live in towns of 4,000 and over, and only 9 per cent in those of 2,000 and over.

There are 75 counties in Arkansas, as follows, with their county seats:

Arkansas, Dewitt.
Ashley, Hamburg.
Baxter, Mountainhome.
Benton, Bentonville.
Boone, Harrison.
Bradley, Warren.
Calhoun, Hampton.
Carroll, Berryville.
Chicot, Lake Village.
Clark, Arkadelphia.
Clay, Corning.
Clebourne, Heber.
Cleveland, Rison.
Columbia, Magnolia.
Conway, Morrillton.
Craighead, Jonesboro.
Crawford, Vanburen.
Crittenden, Marion.
Cross, Vanndale.
Dallas, Princeton.
Desha, Arkansas City.
Drew, Monticello.
Faulkner, Conway.
Franklin, Ozark.
Fulton, Salem.
Garland, Hot Springs.

Stone, Mountainview.
Union, Eldorado
Van Buren, Clinton.
Washington, Fayetteville.
White, Searcy.
Woodruff, Augusta.
Yell, Danville.

Chief Cities.— There are only eight places of 4,000 and over, the three largest being on the Arkansas. The one considerable city is the capital, Little Rock, 38,307; a manufacturing and railroad centre, on the first high ground above the Arkansas bottom lands. The chief of the remainder are Fort Smith, 11,587, where the river emerges from Indian Territory; Pine Bluff, 11,496, half way from Little Rock to the mouth of the river; Hot Springs, 9,973, a noted sanatorium, in the western centre just north of the Ouachita; Helena, 5,556, on the Mississippi below Memphis; and Texarkana, 4,914, in the southwest on the border of Texas.

History.— It has almost none till the 19th century. De Soto's expedition furnished the first white men to set foot on it, and De Soto himself was not improbably buried in Arkansas River. The first French explorers found here an Indian tribe called the Arkansaw, which they spelled in French fashion, Arkansas. In 1685 Bienville's Frenchmen camped for a while at Arkansas Post, in the Arkansas River bottoms near the White and the Mississippi. In 1720, as part of John Law's famous "Mississippi scheme," he was granted by the Regency 12 square miles on the Arkansas River, on condition of settling 1,500 Germans there and protecting them against the Indians; but the scheme ended with Law's failure, and the few who did come settled elsewhere. The district when finally dotted with a few settlements was in French hands till the Louisiana Purchase in 1803, of which it formed part; in 1812 it was made part of Missouri Territory, and in 1819 organized as Arkansas Territory, which included Indian Territory. At this time the entire population, including Indians, was not above 10,000; yet in November 1819 the Arkansas *Gazette* was founded at Little Rock; and settlers began at once to flow in. On 15 June 1836 it was admitted to the Union as a slave State, paired with Michigan as a free State, though the latter's formal admission was a few months later. Though slave and of southern settlement, the hill-country farming divided it in sentiment in 1860, and there was a violent struggle between the Union and secession element; but in January 1861 the latter succeeded in calling a secession convention, by 27,412 to 15,826. The

State officers anticipated them by securing Fort Smith, and the Federal arsenals at Napoleon and Little Rock; but on Lincoln's call for troops, the convention met and on 6 May passed a secession ordinance. In 1862 the Confederate forces were defeated at Pea Ridge, 6-7 March, and Prairie Grove 7 Dec.; Helena and Arkansas Post fell into Union hands, and 4 Sept. 1863, Little Rock was captured and the State reclaimed for the Union. The loyalists then held a convention in January 1864, framed a constitution, adopted it by a purely loyalist vote, elected congressmen and State officers, and organized a regular government; but Congress refused to accept it or admit the State again. Under the Reconstruction Act of 1867, a constitution was adopted in March 1868, and the State readmitted 22 June. Several counties were again put under military rule in 1868. The anarchy under the carpet-bag régime culminated in a civil war in April 1874, in which the United States was invoked. A new constitution was adopted in 1874, under which the State now works.

U. M. Rose,
Ex-President American Bar Association.

Ar'kansas City, Kan., a city of Cowley County, near the southern border of the State, on Arkansas River, near the Walnut River, and furnished with water power by a canal uniting them. It was settled 1870, and incorporated 1872. It manufactures agricultural implements, windmills, wire mattresses, flour and lumber; and has a large trade with Indian posts and agencies in Oklahoma and Indian Territory. It contains a United States Indian School. Pop. (1900) 6,140.

Ar'kansas Post, Ark., a village in Arkansas County; on the Arkansas River; 117 miles southeast of Little Rock. It is on a high bluff and was the site of the first settlement made within the present limits of Arkansas by French missionaries in 1685. Its elevated location gave it considerable military importance during the Civil War. The Confederates established strong works here, which were reduced by a combined assault of a portion of the Federal army, under Gen. McClernand, and a naval command under Admiral Porter, on 11 Jan. 1863.

Ar'kansas River, the largest affluent of the Mississippi save the Missouri; length, nearly 2,000 miles; area of basin, 189,000 square miles; mean discharge, 63,000 cubic feet. It rises in the central Colorado; flows east with a rapid current through deep, narrow cañons, and over a rocky bed till it emerges on the naked, arid plains of eastern Colorado and western Kansas; runs east several hundred miles in Kansas, and turning southeast leaves it near Arkansas City. It then cuts a cantle off Oklahoma and Indian Territory,— where it receives the Cimarron and the broad shallow Canadian from the west, with the Verdigris and Neosho from the north,— and becomes navigable 650 miles to its mouth in Arkansas (which it bisects).

Ar'kansas Stone, a name given to the oilstones made from two grades of novaculite quarried in Hot Springs, Garland County, and also in adjoining counties in Arkansas. The rocks cover a large area and yield the finest whetstones. From them the highest grades of both whetstones and razor hones are made.

Ar'kansas, University of, a State institution organized in 1872, with academic and technical departments in Fayetteville; law and medical departments in Little Rock, and a normal school for colored students in Pine Bluff. At the close of 1901 it had 37 professors and instructors, 1,150 students and 681 graduates. It has a library of 10,000 volumes, and an income of $70,000, while its grounds and buildings are valued at $300,000.

Ark'low, Ireland, a town in the county of Wicklow, 14 miles south-southwest of the town of that name, on the right bank of the Avoca, which falls into the sea about 500 yards below the town, and is here crossed by a bridge of 19 arches. It is inhabited principally by fishermen. There are remains of an old monastery, and of the castle of the Ormonds, the latter destroyed by Cromwell in 1649. Here in 1798 the United Irishmen suffered a defeat. Pop. (1901) 4,172.

Arko'na, the northeast promontory of the German island of Rügen, in the Baltic. Its chalk cliffs rise to a height of 177 feet, topped with a lighthouse, built in 1827, from which the Danish island of Möen, 33 miles northwest, can be seen. Here stood the famous fortification (Slavonic, *Urkan*) so long impregnable, and the temple of the Wend deity Swantewit, the most sacred sanctuary of the Slavs of northern Germany.

Arkose. See Sandstone.

Ark'wright, Sir Richard, a famous English inventor: b. in Preston, Lancashire, 23 Dec. 1732; d. 3 Aug. 1792. He was the youngest of 13 children, and was bred to the trade of a barber. His residence in a cotton-spinning district (Bolton), drew his attention to the operations of that manufacture; but he was 35 before he devoted himself to consideration of the subject. The *spinning-jenny*, invented in 1767 by Hargreaves, gave the means of spinning 20 or 30 threads at once with no more labor than had previously been required to spin a single thread; but the thread spun by the jenny could not, however, be used as warp, being destitute of the firmness required. Arkwright supplied this deficiency by the invention of the *spinning-frame*, which spins a vast number of threads of any degree of fineness and hardness, leaving the operator merely to feed the machine with cotton, and to join the threads when they happen to break. His invention introduced the system of spinning by rollers, the carding, or *roving* as it is technically termed (that is, the soft loose strip of cotton), passing through one pair of rollers, and being received by a second pair, which are made to revolve with three, four or five times the velocity of the first pair. By this contrivance the roving is drawn out into a thread of the desired degree of tenuity, a twist being given to it by the adaptation of the spindle and fly of the old flaxwheel to the machinery. The precise date of his invention is not known; but it is most probable that the idea of spinning by rollers had occurred to his mind as early as the period when Hargreaves was engaged in the invention of the jenny. He removed to Nottingham in 1768, in order to avoid the attacks of the lawless rabble who thought his machines would deprive many workmen of a livelihood. Arkwright erected his first mill, which was driven

SIR RICHARD ARKWRIGHT.

FAMOUS FOR INVENTIONS IN COTTON SPINNING.

by horses, at Nottingham, and took out a patent for spinning by rollers, in 1769. He built a second factory on a much larger scale at Cromford, in Derbyshire, in 1771, the machinery being turned by a waterwheel, and having made several additional discoveries and improvements, took out a fresh patent for the whole in 1775, thus completing a series of ingenious and complicated machinery. When the importance of his inventions became known efforts were made to have the patent set aside, and in 1781 Arkwright commenced actions against a number of persons for invading his patent. Only one cause was tried, that against Col. Mordaunt in the Court of King's Bench in July 1781; and in that the verdict went against Arkwright on the ground of defective specification. In February 1785, a second action was tried in the court of common pleas, in which Arkwright brought a number of persons to prove that they could make machines from his specifications, in consequence of which he obtained a verdict in his favor. This producing great alarm among many who had erected machines for cotton spinning, and from whom a royalty was demanded, in order to settle the dispute a suit was brought against Arkwright in the Court of King's Bench, in which the whole question was argued, not only as to the intelligibility of his specification, but on the less technical and more important ground of his not being himself the inventor of the machines for which he had obtained a patent. After a long and ably-conducted trial a verdict was given against Arkwright, and in November 1785 the patent was cancelled. None of Arkwright's most intimate friends, or those best acquainted with his character, ever had the slightest doubt with respect to the originality of his invention. In 1786 Arkwright received the honor of knighthood from George III., and unlike many inventors, he amassed a large fortune by his inventions.

Arlberg, a mountain pass between the Rhætian and the Lech Alps, in the west of Tyrol; between it and Vorarlberg, pierced by the third longest railway tunnel in the world. It is six and one half miles long, was finished in November 1883, and connects the valley of the Inn with that of the Rhine, and the Austrian Railway system with the Swiss railways.

Arles (ancient, *Arelate*), a town in France on the Rhone, about 25 miles from its mouth. It stands on a rocky limestone eminence, sloping to the river, and has irregular streets, presenting many interesting features. In a large square is an ancient granite monolith, and among other remarkable objects are the Romanesque Cathedral of Saint Trophimus, with a fine portal and some good paintings and sculptures; and especially numerous ancient remains, of which the most conspicuous are those of a Roman amphitheatre, which accommodated 24,000 spectators, and those of a Roman theatre. It has railway workshops, but its manufactures are unimportant, though its trade is important. Arles was founded several centuries before the Christian era and was the chief colony of Massilia (Marseilles). In the 4th and 5th centuries several church councils met here. From 897 to 1150 it was the capital of a kingdom bearing its name. Pop. (1901) 15,506.

Arlincourt, är'län-koor', **Charles Victor Prevôt, Vicomte d',** a French poet and novelist: b. in 1789; d. in 1856. His chief poetical work is 'Charlemagne, or the Caroleid' (1818), an epic; and of his novels the most successful was 'Le Solitaire' (1821), which was translated into all European languages. Among several pamphlets, written in support of the Legitimist cause in 1848, one entitled 'God Wills It' went through 64 editions.

Ar'lington, Henry Bennet, Earl of, an English politician: b. in 1618; d. in 1685. He was a member of the "Cabal" ministry and as Secretary of State was of much influence in public affairs.

Ar'lington, Mass., a town in Middlesex County, about seven miles northwest of Boston. It contains several fine buildings, among which is a library given to the town by Mrs. Eli Robbins at a cost of $200,000. The town has electric lights and car service to Boston. It was settled about 1650 and received its present name in 1867. Pop. (1900) 8,603.

Ar'lington Heights, a range of hills in Fairfax County, Va., on the Potomac, opposite Washington. They were strongly fortified during the Civil War. Gen. Robert E. Lee's estate here is now the site of a national soldiers' cemetery.

Arlon, är'lôn, a town in Belgium, the capital of the province of Luxembourg, in the midst of the woods and mountain ridges of the Ardennes. It is a thriving place, with manufactures of ironware, leather, tobacco, earthenware, and clay pipes. It appears in the Antonine Itinerary, and from the coins, inscriptions, and other antiquities found, must have possessed some importance even in the time of the Romans. It is mentioned under its present name in 870, in connection with the partition of Lorraine. Pop. (1899) 7,997.

Arm, a term technically applied to that portion of the upper extremity of the body extending from the shoulder joint to the elbow, but popularly used to denote both arm and forearm. The arm proper has one large and strong bone, the humerus, covered by strong muscles, which protect the blood vessels and nerves. The upper end of the humerus fits into the head of the scapula and with the clavicle forms the shoulder joint. The head of the humerus is held in the joint partly by ligaments, but mainly by the muscles attached to it. The motions of the arm are many. Those muscles that move the arm inward toward the chest are known as the adductors. These are the pectoralis major, coraco brachialis, which also flex the arm, and the latissimus dorsi and teres major, which also extend the arm. The arm is moved away from the body by the deltoid, a large muscle on the outer side, and the supraspinatus, a smaller muscle going from the scapula. The arm is rotated outward by the infraspinatus and the teres minor, and rotated inward by the subscapularis. All of these muscles are fastened about the upper part of the humerus. The greater mass of the muscles of the arm are those that go to the forearm and that move that member. Those that flex the forearm, or bend the elbow, are the biceps, the brachiates and the brachio-radialis, the former being the most important. It also aids in turning the forearm,

palm downward. The muscles that extend or stretch the forearm are the triceps and the anconeus. There are other movements of the forearm. The arm having two bones, the radius and ulna, one turns on the other and the movements of pronation and supination are produced. Pronation is accomplished by two muscles, the pronator teres and the pronator quadratus; the supinator makes the movement outward. The movements of flexion and extension take place in the elbow joint, which is hinged like those of pronation and supination, just below the elbow joint, the radius moving on the ulna. The union of the radius and ulna with the bones of the wrist make a hinge-like joint, the wrist joint. Movements at the wrist are in four directions, flexion and extension, abduction and adduction. These movements, as well as those of the fingers, are made by a large group of muscles some 20 in number. There are in all 48 muscles concerned in the movements of the arm, forearm, and hand. The blood supply of the arm is derived from the brachiocephalic of the right side and from the arch of the aorta on the left (see AORTA) in a single main trunk that divides at the bend of the elbow. The first portion is called the subclavian and is not in the arm proper, the axillary, or second portion, begins at the outer border of the first rib and becomes the brachial just about the armpit, where it may be felt and compressed. The brachial artery is the great trunk of the arm. It may be felt just inside of the inner edge of the biceps muscle about the middle and there may be readily compressed in case of hemorrhage. At the bend of the elbow the brachial artery divides into the radial and ulnar, which supply the outer and inner sides of the forearm respectively. The radial artery is the one most frequently felt in determining the pulse; the ulnar may be used but as it lies deeper it is felt less easily. In the hand these arterial branches anastomose to form a superficial and a deep palmar arch from which branches go to supply the fingers. Hemorrhages in the palm of the hand can be controlled therefore only by controlling both radial and ulnar arteries, or better, by controlling the brachial just above the bifurcation in the elbow. This may be done by strongly flexing the forearm or something held against the artery. The principal veins of the forearm are the ulnar, the median, and the radial; of the arm the cephalic and the basilic. These empty into the axillary vein, and this into the subclavian. The nerve supply of the arm is derived from the spinal cord from the fifth, sixth, seventh, and eighth cervical, and the first, second, and third thoracic nerves. These form a complex plexus, the brachial plexus. The main branches going to the different muscles and supplying the skin areas are the median, ulnar, musculo spiral, musculo cutaneous, and circumflex. Their distribution is extremely complex.

Armada, är-mā'da or är-mä'da, the Spanish name for any armed force, especially a naval force. The term *Spanish Armada* is applied to that great naval armament which Philip II., in 1588, fitted out under the command of the Duke of Medina-Sidonia and Martinez de Recaldo, against Queen Elizabeth, with the view of conquering England, which Pope Sixtus V. had bestowed upon Spain. The fleet consisted of 131 great and many smaller ships of war, and carried 19,000 marines and 8,000 sailors. The ships had scarcely quitted Lisbon on 29 May 1588 when they were scattered by a storm and had to be refitted in Corunna. Advancing in the form of a half-moon of seven miles in extent, it came in sight, off Plymouth, of the English fleet, scarcely numbering 80 sail, and commanded by Lord Howard, who, endeavored by dexterous seamanship, and the discharge of well-directed volleys of shot at alternately long and short distances, to damage the vessels of the enemy. Some of these, including the galleon laden with treasure, fell into the hands of the English or were destroyed. Arrived at length off Dunkirk, on the 7 August the armada was becalmed and thrown into such confusion by the arrival in the fleet of eight fire-ships sent by the English admiral, that on the morning of the 8th Lord Howard was enabled to attack it on several sides. Notwithstanding a brave resistance, many of the Spanish vessels were destroyed or fell into the hands of the English and Dutch, and in consequence the Duke of Medina-Sidonia resolved to abandon the enterprise, conceiving the idea of conveying his fleet to Spain by a voyage round the north of Great Britain. A hurricane which now broke forth with tremendous violence on the already dispirited Spaniards, scattered their ships in all directions. Some went down on the cliffs of Norway, others in the open sea, and still others on the Scottish coast. About 30 vessels reached the Atlantic Ocean, and of these several were driven by a west wind on the coast of Ireland and wrecked. In all, the armada is said to have lost in the open sea 72 large vessels, exclusive of smaller craft, and 10,185 men, while every family of distinction in Spain had to mourn the loss of one or more of its members. Only about 50 vessels reached Spain on the return voyage.

Bibliography.— Corbett, 'Drake and the Tudor Navy'; Creasy, 'Fifteen Decisive Battles'; Froude, 'The Spanish Story of the Armada'; Gardiner, 'Historical Biographies: Drake'; Green, 'History of the English People'; Motley, 'History of the United Netherlands.'

Ar'madale, the title of a novel by Wilkie Collins (1866). The plot of this, like that of 'The New Magdalen,' and other of its author's later novels, is a gauntlet of defiance to the critics who had asserted that all the interest of his stories lay in the suspension of knowledge as to the dénouement. The machinery is in full view, yet in spite of this disclosure, the reader's attention is held until he knows whether the villain or her victims will come out victorious.

Ar'madil'lo (Sp. dim. of *armada,* armed, referring to its bony shell). 1. A. edentate mammal of the family *Dasypodidæ,* found in South and Central America and notable for its defensive armor. This armor consists of small roundish bony plates, ossified within the skin, and united to form solid shields, one over the shoulders, one over the haunches, and, between these two, transverse bands of movable plates, which protect, but leave freedom of motion, to the trunk of the body. These plates are overlaid by a thin, horny pellicle, and between them grow hairs varying in length and amount with the species, from almost none in some to a coat in others, hiding the shell; and the unarmored

1. Pangolin (Manis pentadactyla).
2. Three-banded Armadillo (Tolypeutes tricinctus).
3. Aard-Vark (Orycteropus afer).
4. Pichiciago (Chlamydophorus truncatus).
5. Tamandua (Tamandua tetradactyla).
6. Great Ant-Eater (Myrmecophaga jubata).

ventral surface is also hairy. The head is provided with a shield entirely separate from that of the shoulders, and in some species even the tail is protected by bands of plates. The various forms of armadillos are distinguished largely by the number of movable thin bands of plates lying between the large fixed anterior and posterior shields, up to as many as a dozen in the cabassous (*Xenurus*). This armor serves the purpose of defense, and some of the tribe (only those of the genus *Tolypeutes,* however), increase its value by exercising the power of rolling themselves up into a ball so that the tender under parts of the body may be completely protected. This ability depends upon the number of bands in the central portion of the armor-case. Although true Edentates, these animals have a few small, useless teeth, without true roots; the tongue is covered with a sticky fluid like that secreted by the tongue of an ant-eater, but it is not protrusile.

The armadillos are timid, nocturnal animals, living on insects, carrion, and vegetable matter; their legs and claws are adapted to burrowing, and, when pursued, they usually bury themselves more quickly than the pursuer can follow them. Only one species (*Dasypus villosus*) is sufficiently adaptable to hold its own when a wild region is settled; the others soon disappear. One of the most interesting of them all is the pichichago (*Chlamydophorus truncatus*), found in Argentina, which lives entirely underground like a mole, and exhibits a peculiar structure in many ways, the body having an appearance of truncation, as if the hinder part had been cut squarely off, instead of ending in curved lines. It is very small, only five to six inches long, while the giant armadillo (*Priodon gigas*) measures three feet, exclusive of the tail. Some of the armadillos range north and south as far as Texas and Argentina; among these is the peba, or nine-banded armadillo (*Tatusia novemcincta*). The family is divided into several genera and the species are numerous and are known as peludos, cabassous, apars, etc., elsewhere described. They are eaten by the South Americans and even esteemed delicate, but their flesh is usually so flavored by the insects and decayed matter which they eat that only a few vegetable-eating species are inoffensive to an unaccustomed palate.

Many forms of fossil armadillos are known from both North and South America, a fossil species of Dasypus having been six feet long. Another genus was *Eutatus*, which had a shield formed of 36 distinct bands, of which the last 12 were soldered together. These lead back to the large group *Gravigrada*. (See also Glyptodon; Mylodon.) Good accounts of the armadillos are given in both the ‘Standard’ and the ‘New (Royal)’ Natural Histories. Consult also Hudson's ‘Naturalist on the La Plata’ (1892); Alston's ‘Biologia Americana Centrali’; ‘Mammals’, (1879–82), with colored plates; Azara's ‘Historia Natural de los Paxaros del Paraguay’ (Madrid, 1805); ‘Mammals of Uruguay’ in the Proceedings of the Zoological Society of London for 1894.

Ar'madil'lo, in entomology. See Wood-lice.

Armageddon, ăr'ma-gĕd'dŏn, the great battlefield where occurred the chief conflicts between the Israelites and their enemies. The name was applied to the tableland of Esdraelon in Galilee and Samaria, in the centre of which stood the town Megiddo, on the site of the modern Lejjun; used figuratively in the Apocalypse to signify the place of “the battle of the great day of God.”

Armagh, är-mä', a county of Ireland, in the province of Ulster. The northern part of the county, bordering on Lough Neagh, consists principally of extensive bogs of great depth, with a remarkably black soil. The manufacture of linen is carried on very extensively. The chief towns are Armagh, Lurgan, Portadown, and Newry. Armagh is the county town. Pop. (1901) 125,238.

Armagh, a city of Ireland, capital of the county of Armagh. It contains two cathedrals, a Protestant and a Roman Catholic; county court-house, prison, infirmary, lunatic asylum, linen hall, music hall, a public library and an observatory. In the Middle Ages Armagh was an extensive and populous city, and celebrated for its learning, having at one period, according to Irish historians, 7,000 students at its college. It is the see of an archbishop of the Anglican Church, who is primate of all Ireland. Pop. (1901) 7,438.

Armagnac, är'ma-nyak', **Counts of,** an ancient French family, said to have sprung from a branch of the Merovingians. Many of its members hold a prominent place in the history of France. One of the most celebrated was Bernard VII., son of John II., surnamed the Hunchback. He succeeded his brother, John III., in 1391, and greatly extended his territories by the most unscrupulous means, putting several of his relations to death because they stood in the way of his ambitious schemes. Another of the family, John V., grandson of the above, who succeeded his father, John IV., in 1450, made himself notorious for his crimes. On a pretended dispensation from the Pope he married his own sister, by whom he had three children.

Ar'magnac', the title of a former district of France now included in the department of Gers. Its inhabitants figured largely in the wars of the Middle Ages, one of their contests being known as the “Armagnac War,” in which the Armagnac mercenaries of the Emperor Frederick III. were defeated by the Swiss, 26 Aug. 1444. See Berthault's ‘L'Armagnac’ (1899).

Armagnac War, The (*Bellum Armeniacum;* in German called frequently *Armegeckenkrieg*), the struggle between the Swiss and the Armagnac mercenaries of Frederick III. in 1444. The war was concluded by the defeat of the Armagnacs at Saint Jacob on the Birs 26 Aug. 1444. See Armagnacs, The.

Armagnacs, The, mercenary bands, derived chiefly from the district of Armagnac in southern France, and largely trained in the army recruited in 1410 by Count Bernard of Armagnac for his contest with the Duke of Burgundy. They made themselves extremely oppressive in France through their plundering; and when the Emperor Frederick III. requested auxiliary troops from Charles VII., to assist in the conquest of the Swiss, the latter gladly despatched the Armagnacs. Doubtless the king believed he might at the same time be able to

gain control of territory on the left bank of the Upper Rhine. What is known as the Armagnac war ensued. In Germany the word Armagnac was converted into *armer Geck* ("poor fool"), and the war frequently styled *Armegeckenkrieg.* One band of 20,000 Armagnacs proceeded by way of Lorraine, another of 30,000 to southern Alsace, whence it marched against the Swiss. At Saint Jacob on the Birs, 26 Aug. 1444, it was badly defeated, with a loss of 6,000, by 2,000 Swiss. It then retired to Alsace, and on 28 October a treaty (that of Ensisheim) was concluded between France and the Swiss Confederation. The Armagnacs continued for a time to work havoc in Alsace and Swabia, where the peasantry retaliated by condemning to death an Armagnac whenever they caught one. In 1445 the remnant was in part dismissed by Charles VII., in part incorporated with other companies of soldiery. Consult the article by Barthold in Raumer's 'Historisches Tascherbuch,' 2d series, Vol. III. (1842); Wülcker, 'Urkunden und Schreiber, Betreffend den Zug der Armagnaken' (1873).

Armançon, a river of France, in the Seine basin. It rises about 3 miles south of Pouilly-en-Auxois (Côte-d'Or), flows about 170 miles in a general northwesterly direction, and empties into the Yonne at La Roche. From Buffon it is followed by the Burgundian Canal. Its tributaries are the Brenne and the Armance.

Armament of the World. Arrangements made for defense with small arms and artillery belong to what is termed the armament. With small arms it is complete when the banquette and the interior and superior slopes are properly arranged to enable the soldier to deliver his fire with effect, and to mount on the parapet to meet the enemy with the bayonet. The armament with artillery is, in like manner, complete when suitable means are taken to allow the guns to fire over the parapet or through openings made in it, and when all the required accessories are provided for the service of the guns. The manner of placing artillery and its employment must be regulated by its relative importance, under given circumstances, with respect to the action of other arms. In the defensive, the principal part is usually assigned to the artillery; and the positions taken up by the other arms will, therefore, be subordinate to those of this arm. In offensive movements, the reverse generally obtains. Unless the batteries are on points which are inaccessible to the enemy's cavalry and infantry, they must be placed under the protection of the other troops, and be outflanked by them. Preparations should be made to receive the enemy on every point; the batteries must be distributed along the entire front of the position occupied, and on those points from which they can obtain a good sweep over the avenues of approach to it; the guns being masked, when the ground favors, from the enemy's view, until the proper moment arrives for opening their fire. Field artillery, used in the operations of an army in the field, must have the essential quality of mobility. The light pieces are constructed to follow the rapid movements of light troops and cavalry. The heavy pieces are employed to follow the movements of heavy troops, to commence an action at long distance, to defend field-works and important positions on the field of battle, etc. Field artillery is used in combination with infantry and cavalry, or with both to augment their fire and to weaken that of the enemy. It prepares the way for subsequent operations by its fire upon the enemy before he comes within reach of other weapons; it supports the movements of the various arms, and forms points of support and assembly for troops when driven back. The armament, small arms and field artillery, in the various countries, now used or, at this time, commended and undergoing experiment with a view to adoption, is set out in detail in this article.

Austria-Hungary.—The infantry is armed with the model 1895 repeating rifle. The technical troops, the field and foot artillery, and the enlisted personnel of the subsistence branches, carry the model repeating carbine (Repetier-Stutzen). The cavalry has the model 1895 repeating carbine (Repetier-Karabiner). All these arms are of the Mannlicher system and have a caliber of 8 millimeters. The Hungarian House of Representatives recently passed a law to arm the landsturm with 8 millimeter repeating rifles. The officers, cadets, and sergeants of the pioneers are armed with revolvers and are independent and capable of defending themselves. Experiments are now being made with the Roth automatic pistol with a view to its replacing the repeating revolver, model 1898, at present in use in the infantry. This pistol is provided with a hammerless firing mechanism and a breech closure composed of two rigid and symmetrical locking lugs and can receive 10 cartridges. The cavalry is partly armed with the model 1870–74 revolver, of the Gasser system, and partly with the model 1898 revolver transformed, this latter being adopted experimentally. Trials have taken place in Austria of machine guns for use with cavalry and for mountain warfare. The gun for the cavalry has a wheel mounting, drawn by a horse. In the mountain section the gun is carried by mules, one animal for the gun itself and two for the ammunition and mounting, and in action is used upon a tripod, variable in height and having a seat for the gunner upon the leg behind the breech. The mountain guns are upon the Maxim-Nordenfelt system, and fire the ordinary infantry cartridge with a rapidity of 500 rounds per minute, and sights graduated from 200 to 2,000 metres. The supply of ammunition carried with the two guns upon the mules provides for 11,000 rounds. Austria-Hungary is experimenting with new artillery material. The long recoil system has been adopted on principle, but the special model has not yet been decided upon. Some batteries of guns submitted by Ehrhardt and Skoda are at present in the hands of the troops. The type of the carriage and whether the caisson should be armored, are two questions now being carefully considered. The gun has been determined to be of 75 mm. caliber, with long recoil on the carriage, and is provided with shields and hinged portions and the interrupted-screw fermeture. With regard to the carriage, very complete and satisfactory tests have held with telescope-trail carriages of the Ehrhardt-Mannesmann system, and with carriages of the Skoda system. Both of the models have been modified and highly improved in the course of the experiments. It is believed that the Austrian War Department, adopting the idea that in battle the caissons will be under cover in rear of the line of pieces in battery, will

give up the idea of introducing armored caissons.

Belgium.—The infantry, technical troops, cavalry, and civil grades are armed with the 7.6-millimeter, model 1889, Mauser rifle. The noncommissioned officers and trumpeters of the mounted arms and the drivers of the field artillery have the Nagant revolver. The officers of the entire army and the noncommissioned officers, "brigadiers," and enlisted men of the gendarmerie carry the Browning automatic pistol. The field artillery consists of 34 regular and 6 reserve batteries, all with 6 guns. They are divided into field and horse artillery batteries. The field batteries, armed with 8.7-cm. guns, are attached to the army divisions; the gorse artillery batteries accompany the cavalry divisions and are armed with 7.5-cm. guns. The first and third field artillery regiments each consist of a staff of 8 regular and 1 reserve battery, plus another reserve battery for furnishing 3 ammunition columns and a depot. The second and fourth regiments each consist of a staff, 7 regular field and 2 regular horse artillery batteries; of 2 reserve field batteries, plus 1 reserve battery, for providing 3 artillery ammunition columns and a depot. Up to the present the Belgian field artillery has consisted of guns of the 1878 Krupp model of 2 calibers — one of 2.95-inch for the horse artillery, and one of 3.42 for the foot artillery. At the beginning of 1900 a committee was formed to decide on the best type for new guns, and as a result of the committee's deliberations a battery of guns of a new type was ordered from the John Cockerill Nordenfeldt Company, at Seraing, in order that the guns might be put to the test of actual use in the army. In these guns the barrel and carriage form, for the purpose of firing, one rigid piece; and this type of gun would probably have been selected for the Belgian artillery had not the new French gun prevented the committee from coming to a final decision. The principle of the French gun is the very opposite to the Cockerill gun, as in its case the barrel slides backward and forward on the carriage.

Brazil.—At the present time the troops carry the 7 millimeter, model 1893, Mauser rifle. Experiments are going forward with a view to partial rearmament, particularly with a view to the adoption of an automatic pistol. Competitive trials were held in 1902 between the Krupp and Creusot types, and according to Brazilian reports these tests have demonstrated the superiority of the German model. Further trials, however, of other types are in progress. Creusot, Krupp, Vickers, and Ehrhardt being in competition.

Bulgaria.—The infantry is armed with the 8-mm. Mannlicher rifle of the 1888 patterns. Each rifle is supplied with 200 cartridges, 100 being carried by the soldier, 50 in the regimental, and 50 in the artillery park transport. Officers and sergeant-majors are all armed with the Smith & Wesson revolver and a Russian-pattern sword. The militia are armed with Berdan rifles and have 80 cartridges per rifle. The cavalry is armed with the Mannlicher carbine and a Russian dragoon sword. Each carbine has 60 cartridges. The Parabellum automatic pistol, model 1903, is being substituted in place of the Smith & Wesson revolver, for officers. Bulgaria has taken no recent steps for rearmament of her artillery. The present field artillery has 8.7-cm. Krupp guns with 120 shots per gun. The reserve artillery has 75-mm. guns with 149 shots per gun, and 90-mm. bronze Russian guns. The mountain artillery has 75-mm. guns with 133 shots per gun. The gunners are being armed with carbines.

Chile.— Like Bolivia, Brazil, Colombia and Uruguay, the troops are armed with the 7-millimeter, model 1893, Mauser rifle; but experiments are now going forward with a view to partial rearmament. Chile seems content with its present field artillery material. This is a light field gun of the Krupp system, with elastic trail-spade, and is well adapted to the local conditions of the country.

Denmark.—The troops are armed with the 8-millimeter, model 1889, repeating rifle of the Krag-Jörgensen system. During the course of 1901 the Copenhagen militia was armed with 8-millimeter, model 1889, rifles, having hitherto had the models 1867–96 breech-loading rifles. A machine gun, invented by a Danish lieutenant and adopted in the Danish army and navy, has a caliber of 6.5 millimeters and a weight of 6 kilograms; the initial velocity is 720 meters. The rapidity of fire is attained by means of a loading frame holding 30 cartridges, which can be fired in two seconds. The rate of fire is thus 300 rounds per minute, including the time required to substitute full loading frames for the empty ones. Experiments of new field guns have been completed, and the firm of Krupp has been commissioned to deliver the new material, excepting the ammunition. The gun is 75 mm. caliber, on the "Rohrrucklauf" carriage, with shield. The weight of the projectile is 6.75 kgs.; initial velocity, 500 meters per second. Rapidity of fire, 15 to 20 shots a minute. Weight of carriage is 1,000 kgs. Weight of gun, including ammunition and limber (44 rounds), 1,800 kgs. The ammunition carts are armored.

France.—The troops are armed with the 8-millimeter, models 1886 and 1893, rifles and carbines. At the normal firing school of the fortified camp of Chalons-sur-Marne experiments were made in the summer of 1902 for the purpose of improving the firearms of the infantry. The object was to do away with the exceedingly sensitive repeating mechanism and to substitute for it a loader which, without impairing the rapidity of fire, would preclude any possibility of the weapons being rendered unserviceable. The latest invention, which is said to have attained good results, is a new projectile called "bullet D." Very satisfactory experiments were carried out with this bullet. Preparations are being made for the manufacture of 30,000 carbines of a new model for the colonial army. It is intended to substitute this new weapon for the models 1886–93 rifles and the model 1892 carbine in the colonial infantry and artillery. The rifle has proved too heavy and cumbersome for the difficult and fatiguing service which these troops have to perform on their extensive expeditions. The old carbine has not shown itself equal to requirements. Not to mention its heavy recoil, in certain cases it does not produce sufficient intensity of fire and therefore does not inflict as heavy losses on the enemy as are necessary. It has, therefore, been decided to adopt a mixed model in which the ballistic qualities of the Lebel rifle and the present cartridge are retained but a different repeating mechanism is used. The experiments with au-

tomatic rifles are being continued uninterruptedly in France. In the spring of 1902 experiments were made with the Mondragon automatic rifle and carbine on the firing grounds of Hotchkiss & Co., at St. Denis, and gave complete satisfaction and proved the superiority of the weapon over all others tested theretofore.

However much opinions may differ regarding the military utility of automatic rifles, there is certainly a manifest tendency toward increasing the rapidity of fire of small arms to correspond with the improvements that have recently been made in rapid-fire cannon. The automatic rifle bids fair to become the weapon of the future. Germany and Italy already have a model which is by no means inferior to the Mondragon rifle as a military weapon. These models, however, are being carefully preserved in arm depots. The authorities are ready to begin their manufacture and to arm the troops with them as soon as France has set the example. Most foreign officers have acknowledged the superiority of the automatic rifle, but its adoption is being indefinitely deferred because it would entail an enormous burden on the military budgets of the European countries.

The French field batteries have been armed with the new 75 mm. rapid-fire material since 1897. This is a long recoil field gun with protective shields and was manufactured with great secrecy in the government work shops at Brouges. Although the secret of the details of construction is not divulged, it is nevertheless known that this gun possesses great ballistic power, and that its projectiles weigh somewhat more than those of similar guns constructed elsewhere. Its only disadvantage appears to be the weight of gun and carriage. Criticism has also been made of the shields used, as presenting rather a reduced amount of surface for the protection of the cannoneers. The pneumatic recuperator is about to be given up for a light rapid-fire gun suitable for the horse artillery.

Germany.— The marine infantry, the infantry regiments of the East Asiatic brigade of occupation, the guard corps, and parts of the first to seventh, ninth, eleventh, twelfth, fourteenth, and eighteenth army corps, and of the noncommissioned officers' schools are armed with the model 1898 rifle. The issue of the model 1898 carbine has been begun. A new weapon (a sort of carbine) will be purchased for the foot artillery after the rearmament of the infantry is completed. All the remaining organizations of the German army now carry the model 1888 rifle or carbine. The small-arms and ammunition factory of Adolph Loesche at Magdeburg, has placed a target rifle on the market which is in use in several infantry regiments with great success. Three kinds of cartridges are adapted to this rifle. Experiments are now in progress with the Borchardt, Mauser, Mannlicher, Parabellum and Browning automatic pistols.

Germany is now inclining to the new long recoil system in artillery. Although the minister of war maintains his opinion before the reichstag of the superiority of the German elastic trail-spade type over the French long recoil, Germany, nevertheless, continues the process of transformation or suppression of the model 1896. The necessity for rearmament is appreciated and desired, but such haste was made in adopting the model 1896 material with elastic trail-spade that financial considerations prevent Germany from undertaking at present a completely new rearmament of the field artillery. The result is that trials are now going on to change the field guns, model 1896, into long recoil guns by an adaptation of recoil on the carriage to the present gun, that is to say, while keeping the gun itself, a carriage has been designed with a cradle for the piece. The carriage has also been fitted with protective shields. The guns thus modified do not possess the double-laying arrangement applied to the cradle or top carriage. The gun itself retains the rear sight and fore sight, and the changes that have been made affect principally the carriage. According to the German press, the results have been satisfactory both in regard to acting during firing and in maneuvering facilities. In spite of the added weight of the shields, the total weight does not exceed the usual limits. Thirty-six of these altered guns are in the hands of troops, attached in part to the guard at Berlin, three batteries, and in part to the Field Artillery Shooting School at Juterbog. Five batteries have taken part in last autumn's maneuvers and have given satisfaction. In addition to the foregoing, Germany is also engaged in conducting trials of new long recoil types. The Ehrhardt new model, 1899, has been found inadequate and Krupp's model, 1900, has proved better. Two of these guns were tested in 1902 by an artillery commission and resulted in orders being given for seven trial batteries, which were thoroughly proved under service conditions in 1903, and were found to be very satisfactory, but the design was modified slightly and submitted for further test. The Krupp gun chosen is similar in all particulars to that adopted by the Swiss, and like that model constitutes one of the best of the recently constructed rapid-fire systems.

Great Britain.—The European and the greatest part of the Indian native troops carry the 7.7-millimeter Lee-Metford rifle, model 1889–91, and the models 1895 Lee-Enfield rifle; the remainder of the Indian native troops are still armed with various old models, among which are the Martini-Henry and Snider rifles, while certain select corps and the military police on the northwest frontier carry Mauser rifles captured in South Africa. The unmounted officers of the foot troops carry the Lee-Enfield carbine, while the other officers are armed with the revolver. The contemplated improvements in the Lee-Enfield rifle shown to be necessary in the South African war appear to be essentially as follows: The barrel will be shortened by 127 millimeters and will thus be the shortest barrel possessed by any rifle yet adopted. In order to compensate for the decreased stability of the projectile caused by this shortening of the barrel, the seven rifling grooves are to be given a somewhat higher pitch, so that the trajectory will remain similar to the previous one. The Mauser breech-closing mechanism has been adopted, with some improvements enabling it to be taken apart without the use of a screw-driver. It will be fed by means of a loading clip containing five cartridges. The sight has been improved and provides for an allowance for wind and temperature. A triangular dagger bayonet 35 centimeters long and slightly heavier than the present one has been adopted. In order to

lighten the weapon holes are bored longitudinally through the handguard and transversely through the stock, the butt plate being of aluminum. The total reduction of weight amounts to .530 kilogram, leaving the weight of the rifle 4.12 kilograms. Experiments with the Ross straight-pull breech closure, the Harris magazine, and the Hylard rifle do not appear to have resulted favorably. Canada has, however, decided to adopt the Ross rifle, and both rifle and ammunition are to be manufactured in the government factory at Quebec, the number of rifles to be turned out yearly being from 12,000 to 15,000. The length of the Ross rifle without bayonet is 1.22 meters, and with bayonet 1.44 meters; the weight without bayonet is 3.43 kilograms; with bayonet 3.74 kilograms. The Australian colonies appear to have decided to adopt the Ross rifle. Major Woodgate, of the British army, has recently invented a new system of automatic rifle, which is very simple and capable of adjustment to rifles already in service, including the Lee-Enfield. The chamber of this rifle has a capacity for 20 cartridges (10 being the normal number), so that the number of rounds per minute can be brought up to 200.

In artillery England has 18 batteries of Ehrhardt rapid-fire guns, of 3-inch caliber, firing a projectile weighing 14 pounds 15 ounces. The carriage has a hydraulic buffer with spring recuperators for returning the piece in battery, and a telescopic trail. After several years of experiment, a long recoil gun, combining the best qualities of recent designs by Armstrong and Vickers, and much superior to the former 15-pounder, has been adopted. The new gun is exceptionally powerful and efficient. The improved time fuse permits of effective shrapnel fire at a range of 6,000 yards, an enormous advance on anything possible with the old type of field gun. There are four special points in which the new type surpasses the old. These are simplicity of the breech action, in which the interrupted screw is abolished, increased range, vastly increased rapidity of fire, and perfect absorption of the recoil. In the old type of gun a coned steel block carrying an interrupted screw thread was used to close the breech, and intricate and comparatively delicate mechanism was necessary to work it quickly, while the danger of barring or injuring the screw threads when inserting the shell necessitated an amount of care which materially interfered with the loading of the gun.

Greece.—The infantry is armed with the 11-millimeter, model 1871, Gras rifle; but experiments are in progress to decide upon a rearmament with a small caliber rifle. For financial reasons, Greece has not made any decision as regards the rearmament of field artillery.

Italy.—All the infantry of the line and the mobile militia are armed with the model 1891 rifle, the cavalry with the model 1891 carbine, and the special arms with the model 1891 carbine (Stutzen), all of the 6.5 millimeter caliber. The territorial militia carries the modified Vetterli rifle, caliber 10.4 millimeters. A new pistol, embodying all the latest improvements, has been adopted for the officers of the army in place of the 10.35-millimeter, model 1889, revolver. It has an automatic mechanism, is of small caliber, and fires smokeless powder. The loading is done in the same manner as the model 1891 rifle. The field gun question in Italy has long been a subject of controversy. Discussion of the question of the proper type of new material has been vigorously conducted on both sides by critics and leading military writers, but the Italian army, it seems, is the one that has remained for the longest time averse to the idea of a field gun with long recoil on the carriage. As is known, the Italian field artillery consisted of two calibers of guns, the 87 mm. B, of steel, forming the armament of the larger part of the batteries, and the 75 mm. B, of bronze. In 1896 and 1897 when France and Germany effected the transformation of their field material a partial transformation was decided upon in Italy. For the material 87 mm. B, the cast-iron shrapnel was retained, and the changes made were confined to limiting the recoil of the piece by the addition of a trail-spade, and to increasing the rapidity of loading by improvements in the breech mechanism.

Japan.—All the infantry is armed with the 6.5 millimeter 30 Meiji rifle, and the cavalry with the Meiji carbine. The weight of projectile of the new rifle is 10.3 grams, and the velocity of the bullet at 25 meters from the muzzle is 706 meters. The Mourata guns of the 1880 and 1887 types arm the troops of the second line. The new gun of Col. Arisaka, model 1897, manufactured at the Tokio works, like the Russian gun, is a repeater of small calibre (.25 inch) with a central magazine for five cartridges. It belongs to the Mauser type. The barrel is 31 inches in length and is provided with six grooves turning from left to right. The breech sight is mounted upon it by means of a long sleeve, the upper part of which, flattened and hollowed, forms its foot. The prismatic muzzle-sight is secured to a small hoop surrounding the barrel. The movable breech is of the bolt system, and turns back upon the side. The magazine, closed at its lower part by a cover, contains an elevating plate actuated by a spring. The recharging is done by means of a brass charging plate provided with five cartridges. The breech sight, without steps, is graduated from 400 to 2,000 yards. A sabre-bayonet having a 21-inch blade, with bevelled and hollowed sides, is attached in the usual manner. The cartridge weighs 336 grains. The initial velocity is 2,378 feet and the pitch of the trajectory is 387 feet at 500 yards. The gun, with the bayonet, is 5.44 feet and weighs 9.6 pounds. The Japanese foot soldier carries 120 cartridges, partly in two cartridge boxes and partly in boxes in the knapsack. Japan seems very well satisfied with their Arisaka gun for artillery use, and nothing has appeared of any steps being taken towards the introduction of a new material.

Mexico.—The infantry is armed with the 7-millimeter, model 1893, Mauser rifle, and the cavalry with the 7-millimeter Mauser carbine. There are probably about 10,000 modified Remington rifles (arranged for Mauser ammunition) and 15,000 Remington rifles of larger caliber on hand. It is doubtful whether the rifle, which was first manufactured in the French rifle-factory at Saint Etienne, really possesses the qualities attributed to it, namely, absolute reliability, accuracy, and a rate of fire of 60 rounds per minute when used automatically. According to trustworthy reports a rate of fire of 13 to 15 shots per minute was attained during ex-

periments made in Mexico with the Mondragon rifle used as a repeater in aimed fire; in filling the magazine the marksman had to place the rifle against his thigh, probably in order to overcome a strong resistance of the lock mechanism. When used as an automatic arm a rate of 31 shots per minute was attained only once, which resulted in injuring the breech mechanism. The latter is said to get out of order very easily, and, moreover, the muzzle jumps at every shot, so that the accuracy cannot be very great during automatic rapid fire. In artillery Mexico has carried out long competitive trials and at their conclusion, after having ordered four batteries of guns from Creusot in 1902, asked Saint Chamond in 1903 to submit a model of the Saint Chamond-Mondragon type modified according to the desires of the Mexican commission. If this type proves satisfactory, eight batteries are to be ordered at once.

Montenegro.—This principality has 30,000 Russian three-line repeating rifles and 80,000 rifles of various other systems, principally Berdan and Werndl rifles. The enlisted men of the first seniority are armed in peace with one new and one old rifle each. The field artillery consists of the Krupp steel gun, caliber 75 mm.

Netherlands.—All troops are armed with the 6.5-millimeter, model 1895, Mannlicher rifle and the 9.4-millimeter, model 1873, revolver, Chamelot-Deloigne system. The 6.5-millimeter rifle fires a bullet weighing 10.15 grams with an initial velocity of 723 meters. The present field artillery dates from 1878, and no longer fulfills the ballistic and other technical requirements of the present day. The necessity of rearmament was taken under consideration in 1901 and models were entered by Ehrhardt, Schneider-le-Creusot and Krupp. It has been determined that Krupp's 75 mm. long recoil gun deserved the preference and the same has been recently recommended for adoption and a contract for 204 field guns of this type is now pending. The adopted type is the Krupp nickel-steel field gun with long recoil on the carriage; its length is 30 calibers, and it is provided with nickel-steel shields 3 to 4 mm. thick. It fires shrapnel and explosive shell weighing 13.2 pounds, fixed ammunition being used. The muzzle velocity is 1,640 f. s., rapidity of fire 20 shots per minute. The shrapnel contains 270 bullets, each weighing 11 grams. The extreme range is 7,000 yards, and that for shrapnel with time fuse 6,125 yards. The unlimbered gun weighs with shields and complete equipment not quite 2,200 pounds. Each gun with its limber and 3 caissons counts 336 rounds. The introduction of this material will be completed by the end of 1906.

Norway.—The infantry is armed with the 6.5-millimeter, model 1894, Krag-Jörgensen rifle, which fires the model 1896 cartridge. Experiments, concluding in 1891, were made with models of long recoil guns from Armstrong, Hotchkiss, Nordenfelt-Cockerill, Saint Chamond, Schneider-le-Creusot, and Ehrhardt, and finally gave preference to the last named. The program of the tests was very thorough and severe. It included firing 350 rounds from each gun, transportation over long distances both by rail and in ordinary carts over mountainous country, in which the material received much rough treatment, more firing tests and finally a long march over difficult country and under varied conditions. The final firing showed that the material was in good condition, all the parts functioned well, and the hydro-pneumatic brake was in perfect order. Norway has obtained 132 guns of the Ehrhardt system and 72 caissons. As in the case of France, the adopted gun has the disadvantage of being rather heavy, 2,209 pounds, without any shields. The question of shields has only been considered after the guns were ordered, so that its weight makes the problem of providing it with shields a difficult one.

Portugal.—The infantry of the active army and of the first reserve is armed with the 6.5-millimeter, Mannlicher rifle; the infantry of the second reserve is armed with the 8-millimeter, model 1886 Kropatschek rifle; and the colonial infantry and artillery and the cavalry carry the 6.5-millimeter Mannlicher carbine. The only modern field artillery Portugal possesses are two horse batteries having guns with elastic trail-spade carriages. The government sent a special commission some time ago to different countries to gather information from the prominent gunmakers. This commission has submitted its report, on the strength of which it has been decided to make conclusive trials in Portugal with some proposed constructions by Krupp and Schneider.

Russia.—The active and reserve troops are armed with the three-line rifle (7.62 millimeters), model 1891, and the cavalry with the 7.62-millimeter, model 1896, Cossack carbine. The 7.62-millimeter Nagant six-shooter, non-gas-leaking revolver has been officially adopted and is manufactured in the Belgian arm-factory by Leon Nagant at Lüttich. The extensive small arm factories in Russia are those of Tula, Sestrorietsk, and Ijevsk. They not only manufacture rifles, but all other kinds of war stores. The 3-line (.275-inch) gun of the 1891 model is the invention of Col. Mossine of the Russian artillery and is a repeating arm with a central magazine for five cartridges. The barrel has four grooves directed from left to right and is 30 inches in length. The breech box, screwed to the rear of the barrel, is provided on the side to the left with a piece that acts as cartridge shell ejector and isolator. The movable breech is of the bolt type and swings back at the side. The magazine contains the elevating mechanism, formed of a lever joined to the cover and a plate jointed to the lever. It receives a loader provided with five cartridges. The breech sight is stepped and provided with a slider, which is held in place by a spring and serves for indicating distances. The bayonet comprises a quadrangular blade and remains fixed to the end of the barrel, even during firing. The cartridge weighs 590 grains. The initial velocity is 2,035 feet and the pitch of the trajectory at 1,970 feet is 72 feet. The length of the gun with bayonet is 5.7 feet and weighs 9.5 pounds. The Russian soldier carries 120 cartridges, partly in two cartridge boxes and partly in the knapsack. After protracted experiments Russia has provisionally chosen for the field artillery a type of gun and carriage designed by General Engelhart. A large part of the Russian field artillery has been armed with this new gun constructed at the Poutilov works. The gun, together with the cradle that supports it, recoils on the lower carriage, and the recoil is controlled by a glycerine brake, and a column

of rubber buffers fitted in the trail. These rubber cushions act as return springs to return the gun in battery. This gun is of great ballistic power, but the same objection is raised against it as in the case of the French and Norwegian material, its great weight. Nor is the carriage provided with shields. Whether the caissons are to be armored is not known, though the regulations prescribe placing them beside the pieces in action.

Servia.—The infantry carries the 7-millimeter, model 1899, Mauser rifle, and million rounds of ammunition for this rifle has been purchased. The engineers, fortress artillery, and militia have a reserve of Berdan and Peabody rifles. The cavalry carry Mauser-Kota carbines and swords. The artillery is armed with 80 mm. de Bange guns, and has, in addition, 60 Krupp and 40 mountain guns. The gunners are armed with the same rifle as the infantry. The siege artillery has 90 guns of six different types, and in the fortress artillery the difference of the systems is even more marked. Up to the present time, the trials contemplated in Servia have been only with a battery of Skoda guns. They were being begun at the time of the assassination of King Alexander. Additional trials are now contemplated.

Spain.—The Spanish army is armed with the 7-millimeter Mauser rifle. In artillery Spain after prolonged trials ordered three years ago from Saint Chamond and from Krupp 120 guns of a transition type. The carriages are equipped with hydraulic brakes, have a trail-spade, and there are spring recuperators under the body of the carriage. This material was delivered about two years ago. At about the same time 24 field pieces with long recoil on the carriage were ordered from Creusot, which were accepted only after much delay due to the failure of the material to meet the requirements of the Spanish artillery. Recently the Spanish government opened a new competition for guns with long recoil on the carriage, but it seems that no decision has been arrived at as to the type to be adopted for the field artillery. It is reported that the idea of experimenting at home has been given up, and a special board of information has been sent to France, England and Germany.

Sweden.—The infantry is armed with the 6.5 millimeter, model 1896, rifle, and the cavalry with the model 1896 carbine, both of the Mauser system. In order to replenish the supply, 350,000 rifles and 50,000 carbines of the above-mentioned models are to be purchased for the Swedish army. When recent artillery trials began in Sweden, Cockerill and Krupp were the only competitors. The two French firms, Schneider and Saint Chamond, found it impossible to fill the specifications as to the weight of the unlimbered gun. The Krupp long recoil material was adopted for the field artillery, and Sweden has ordered 132 guns and 66 caissons from Essen. For the horse artillery the Krupp short recoil material was chosen, and 24 guns with elastic trail-spade have been bought from the Krupp works.

Switzerland.—The infantry has the 7.5-millimeter, model 1889–96, Schmidt-Rubin rifle; the cavalry carries the 7.5-millimeter, model 1893, rifle, with Mannlicher breech closure; the position artillery, fortress troops, telegraph companies, balloon company, and cyclist detachment are armed with the 7.5 millimeter, model 1889–1900, short rifle; the cadets have the 7.5-millimeter, model 1897, cadet rifle; the officers carry the 7.65-millimeter, model 1900, pistol; the noncommissioned officers and buglers of the élite cavalry and artillery are provided with model 1882 revolvers; the remainder have the model 1878 revolvers. A spirited controversy has arisen in regard to the qualities of the recently adopted model 1900 automatic pistol (Parabellum). The arguments advanced are specially worthy of interest as affording an idea of how the Parabellum pistol behaves in actual service, Switzerland and Belgium being the only countries that have thus far adopted an automatic pistol to any great extent. The general impression gained is that in changing from a revolver to a pistol the troops did not perhaps receive adequate instructions as to the management of the latter, so that a number of accidents occurred which were rather due to the ignorance of the possessors regarding the weapon than to any inherent defect in the weapon itself. From a circular issued by the chief of artillery forbidding the making of any changes in the pistol by private armorers it appears probable that the accidents which have occurred are attributed to such changes. In the recent Swiss trials of artillery nearly all the leading gun factories of Europe competed and Cockerill, Ehrhardt, Krupp, Schneider and Skoda furnished their latest models. Saint Chamond accepted the invitation to compete, but did not deliver its gun in time and did not participate in the trials. Later on this gun was inspected at Saint Chamond but without result. In fact, the artillery commission on field artillery rearmament has during the last six years submitted all the models that it has been able to procure and experiment with, to most searching examination and most thorough tests under all conditions. The final trials commenced in 1901, and in March 1903 the commission submitted its report declaring that the Krupp 75 mm. long recoil model was not only the most satisfactory in all respects and the best of all the models tested, but that it was the best adapted for service in the field. The Federal Council addressed a message to the Federal Assembly on 1 May 1903, deciding on the adoption of the new gun, and in that year the Swiss government ordered from Krupp 288 guns, with which it is proposed to arm 72 batteries of 4 pieces each. This does not include reserve material and that for instruction purposes. The material adopted, officially designated "field artillery material, 1903," is Krupp's latest design of long recoil field gun with spring recuperator and shields. The question of the exact dimensions of the shield is deferred for the time being; the size may be reduced and the side wings dispensed with. It was decided by the commission to armor the caisson bodies. Fixed ammunition is used. The larger part will consist of shrapnel with combination fuses, that being considered the principal projectile, but the batteries will also be provided with explosive shell with percussion fuses. All projectiles will have the same weight. The ammunition supply will be 800 rounds per gun. The commission also studied the question of field howitzers, making trials of different models submitted by Krupp and Skoda, and decided in favor of one of 12 cm. caliber, but the particular

model is still to be selected. The commission was of the opinion that the introduction of a howitzer for the Swiss artillery should not be made at the price of reducing the number of field guns. It estimated that there was necessity for the purchase of 8 batteries of 4 pieces each, constituting 4 groups of 2 batteries. For the howitzers, the ammunition supply will be 500 rounds per gun. In regard to mountain guns, the commission has conducted several tests of a Krupp gun of a system similar to that of the field material, 1903. Although the results obtained thus far have been satisfactory, it has been thought best to continue the experiments with two pieces in which certain modifications of details have been made.

Turkey.—The cadres of the European army corps (first, second, and third) are armed with the 7.65-millimeter Mauser rifle, the fourth corps (Asia Minor) has the 9.5-millimeter Mauser magazine rifle, and the troops of the other corps carry the 11.4-millimeter Martini-Henry and Peabody rifle. The manufacture of the 7.65-millimeter Mauser rifles in Turkish shops has encountered difficulties, for, according to authentic reports, 200,000 rifles of caliber 7.5 mm. were ordered in Germany at the end of 1902. The Turkish field artillery consists of 248 batteries, of which 18 are field, 178 horse, 46 mountain, and 6 howitzer batteries. It is said that 9 more batteries are in course of formation. Without having any recent trials at home, Turkey has ordered from the Krupp works 184 guns with which it is intended to equip 16 batteries of 6 pieces each, and 22 batteries of 4 pieces. These guns are of the modern long recoil system. The order included all accessories, caissons, battery wagons, ammunition and harness. The government is now urging the delivery of the first six batteries constructed. Turkey has in the past sent several delegations to Essen and on two occasions also to other workshops. A military commission of prominent officers of the sultan's army is now in France visiting the establishments of Creusot and Saint Chamond in order to study the most recent models of long recoil rapid-fire guns.

United States.—The new Springfield magazine rifle, possessing numerous improvements on the Krag-Jorgensen rifle, is now under construction and will be placed in the hands of all troops, regular army and National Guard, as rapidly as possible. The principal points of its difference from the Krag-Jorgensen are the use of two lugs instead of one for holding the bolt against the rearward pressure of the powder, with resulting increase of strength sufficient to enable a velocity of 2,300 feet per second to be obtained; the housing of the magazine in the stock directly below the chamber instead of having its project to one side. In addition to these there are various changes of details which both improve the rifle and cheapen and accelerate its production. The arm is supplied with a cleaning rod which can be partially pulled from its place below the barrel and held with a catch so as to form a bayonet. Its great advantage is that it lightens the weight made up of the gun, bayonet, and bayonet scabbard, and by dispensing with the latter two as separate articles to be carried permits the soldier to carry with him an intrenching tool of sufficient size and weight to be serviceable. There are differences of opinion as to the value of the rod bayonet; although less effective as a bayonet alone than the one now in use in the service, it is undoubtedly of some value in converting the musket into a pike, and in view of the increasing prominence of the intrenching tool and the decreasing occasion for the use of the bayonet its experimental substitution is in line with apparent progress in subordinating the latter to the former. The piece is centrally fed by means of clips, each of which holds five cartridges. It has a caliber of .30 inch, and the rifling is made up of four grooves of a depth of 0.004 inch, the twist being one turn in 10 inches. The bullet weighs 220 grains, which is the same as that of the Krag-Jorgensen, but the powder charge has been raised from 37.6 to 43.3 grains. In spite of the considerable increase in its power the weapon has been greatly reduced in weight; for while the Krag-Jorgensen rifle weighs 10.64 pounds, the Mauser 10.5 pounds, and the German military rifle 11.54 pounds, the new weapon weighs only 9.47 pounds. It follows, as a matter of course, that, with such high velocity and fairly heavy bullet, the trajectory is correspondingly flat, the maximum ordinate of the 1,000-yard trajectory being only 20.67 feet as against 25.8 feet for the Krag-Jorgensen gun, a very material difference. The cartridge for the .30 caliber arm consists of the case, bullet, primer and charge of smokeless powder. The case has a flanged head, primer seat, conical body, shoulder, cylindrical neck, and is made of brass. The bullet is lubricated, and has a core of lead and tin composition jacketed with cupro-nickel; it has three grooves, and the mouth of the case is crimped into the front groove to secure the bullet in place. The core is composed of 1 part of tin and 25 parts of lead by weight; this proportion is varied slightly in order to keep the weight of the finished bullet constantly at 220 grains. The primer is composed of a cup, made of cartridge copper and containing the composition, a water-proofed paper disk, and a brass anvil. In plan, the anvil is a circle with two small semicircular portions removed from opposite sides; these two openings form vents for the passage of the flame from the composition to the powder. The powder is of the nitroglycerine type. Up to the present time three different powders have been used (Peyton, Du Pont and Laflin & Rand, W. A.). The charge varies with the powder used from 35 to 42 grains. The primer composition is known as H-48, and consists of 8.63 per cent sulphur, 25.12 per cent antimony sulphide, 49.61 per cent potassium chlorate, and 16.64 per cent glass crystals. The weight of the cartridge complete varies from 435 to 442 grains. The standard instrumental velocity, at 53 feet from the muzzle, of this ammunition in the rifle, is 1,960 feet per second, with an allowed variation of but 15 feet per second on either side of the standard. This instrumental velocity at 53 feet corresponds to a muzzle velocity in the rifle of about 2,000 feet per second. The velocity in the carbine is 80 feet per second less than in the rifle. Experiments with automatic pistols and their trial in the hands of troops are in progress, but the conflicting reports of the advantages and disadvantages of the weapons issued for trial have not been such as to warrant the abandonment of the present service revolver for any of the types tried.

Work upon the lately adopted 3-inch field artillery material is progressing rapidly. There are under construction 25 batteries for the regular service and 16 for the militia. The caisson for the material differs from that in use with the 3.2 inch B. L. rifle in being a metal fabrication, and in having a single chest, instead of two, upon the caisson body, and the omission of means for carrying spare wheels, these latter being transported on the combined forge and battery wagon. The manufacture of 90 mountain guns, carriages and pack outfits of the Vickers Sons & Maxim system, with several suggested improvements, is in progress. The aparejo to be used is a modification of the former regulation pattern, with a view to facilitating packing and general adaptability. Experiments and investigations are now active with a view to bettering the mountain, field, and siege artillery, and machine and automatic guns, of which the famous Gatling is the pioneer. The models in use at the present time are the 1.456-inch (37-millimeter, 1-pounder) automatic gun, 1.50-inch revolving cannon, 1.65-inch B. L. mountain gun, 2.95-inch Vickers-Maxim mountain gun, 3-inch Hotchkiss mountain gun, 3.2-inch B. L. rifle, 3.6-inch B. L. rifle, 3.6-inch B. L. mortar, 5-inch B. L. siege rifle, 7-inch B. L. howitzer, and 7-inch B. L. mortar, together with a variety of pieces used for saluting purposes and for firing the morning and evening guns at posts. These latter are nearly all of the old 3-inch, wrought-iron type, or 12-pounder bronze smooth-bores.

Sea Coast Artillery.—It is only recently that we have become accustomed to the term "Sea Coast Artillery." A few years ago all guns were comparatively small, using the same propelling agent and firing spherical projectiles. Not long ago, any siege gun would have been serviceable against the wooden ships of the day. To-day, all countries have sea coast guns to resist naval attacks and siege guns for the reduction of fortified positions. It is not improbable that the United States may be soon called upon to use sea coast guns, while it is difficult to imagine circumstances under which we might employ our siege artillery. In Europe — that is, on the continent — sea coast artillery is unimportant; for there, war consists practically of land fighting and consequently the field artillery comes prominently forward. France and other countries have a mongrel lot of obsolescent guns in their shore defences, while they have recently spent millions of dollars for rapid-fire field pieces of the latest designs. Twenty-five years ago the propelling agent was black powder; and, in loading, the powder charge, the projectile and the primer were separately put in place. Now these are in one piece, smokeless powder is used, and great improvements in the breech mechanism have wonderfully increased the rate of aimed fire. The control of the recoil and the universal use of shrapnel is a great step toward the possibility of disabling an antagonist before he can fire a shot in return.

The rapid fire and sea coast guns of the United States, at present in use, many of which are almost obsolete, are the 6-pounder American Ordnance Company gun, the 6-pounder Driggs-Seabury gun, the 15-pounder gun, the 4-inch Driggs-Seabury gun, the 4.72-inch Armstrong gun, the 6-inch Armstrong gun, the 5-inch Ordnance Department gun, the 6-inch Ordnance Department model 1897 gun, the 6-inch Ordnance Department model 1900 gun, the 8-inch B. L. R. gun, the 10-inch B. L. R. gun, the 12-inch B. L. R. gun, the 12-inch B. L. M., cast-iron body gun, and the 12-inch B. L. M. steel gun. These guns, together with several experimental, including the 10- and 6-inch Brown segmental tube wire guns, the 6-inch wire-wound gun (Ordnance Department design), and a 6-inch Bofors R. F. gun with semi-automatic breech action constituting our coast armament of to-day, are far from satisfactory and invite the development and substitution of new features. The 16-inch gun, called for by the Fortification Board in 1885, has been recently constructed. As no gun of this power has heretofore been built, and as a special powder had to be made for it, the test was watched with much interest. It was designed to fire a 2,400-pound projectile with a muzzle velocity of 2,300 feet per second and a powder pressure not exceeding 38,000 pounds per square inch. The proof firing was attended with entire success. At the fourth round with a charge of 640 pounds of Du Pont's smokeless powder and a 2,400-pound projectile, a velocity of 2,317 feet per second with a pressure of 36,700 pounds per square inch was attained. That the design and construction of such a huge weapon should be successfully accomplished without a mishap of any kind, and that the calculated ballistic results should be so accurately verified, are subjects of gratification. The use of smokeless powder in such large charges was beyond the experience of the world, and the demonstration that it would when so used follow the same law of burning as with charges of the size previously employed is a service to the art of the construction of ordnance. Whether this gun will be reproduced for use in sea coast fortifications is a matter still to be determined; there are at present no plans calling for its installation, but it is satisfactory to know from the results of actual trial that, in considering at any time the desirability of employing guns of greater power than those of the caliber, 12 inches, now constituting our most powerful weapons, the subject need not be complicated by the question of practicability.

CAPT. EDWARD S. FARROW,
Late Assistant Instructor of Tactics at the United States Military Academy.

Armand, är'mäñ, **Charles Teffin**, a French soldier: b. in 1753; d. in 1793. Coming to America in 1777, he was given a colonel's commission in the American army, succeeded Pulaski in command of the "Pulaski Legion," in 1779, and became a brigadier-general in 1783. Returning to France he was active on the Royalist side in the French Revolution.

Armande, är-mänd', an elder sister of Henriette in Molière's 'Les Femmes Savantes.'

Armansperg, är'mans-perg, **Joseph Ludwig, Count von**, a Bavarian statesman: b. in 1787; d. in 1853. He was president of the regency of Greece, 1833–5, and chancellor of state, 1835–7.

Armatoles, är'mä-tōlz, bodies of Greek militia inhabiting districts in the mountains of Greece assigned to a *capitani* for protection before Greece became independent of Turkey. To

these fastnesses fled the independent part of the Greeks, in order to continue the war under leaders called *capitanis*. A capitani collected generally a troop of from 50 to 200 men, who remained true to him through every variety of fortune, and attacked the enemy everywhere. Thus involved in an endless struggle with their oppressors, these Greeks were apt to degenerate and become little better than bandits. A large number of them were careful to confine their depredations to Mussulmans; but many instances occurred in which Greeks were attacked when the booty expected was considerable. The Turkish pashas, unable to subdue the armatoles, generally treated with them; and the capitanis received, on condition of remaining quiet, money, stores, or other perquisites.

Ar'mature, a term applied to the piece of soft iron placed across the poles of permanent or electro-magnets to receive and concentrate the attractive force. In the case of permanent magnets it is also important for preserving their magnetism when not in use, and hence it is sometimes termed the keeper. It produces this effect in virtue of the well-known law of induction, by which the armature, when placed near or across the poles of the magnet, is itself converted into a temporary magnet with reversed poles, and these, reacting upon the permanent magnet, keeps its particles in a state of constant magnetic tension, or, in other words, in that constrained position supposed to constitute magnetism. A horse-shoe magnet should therefore never be laid aside without its armature; and in the case of straight bar-magnets, two should be placed parallel to each other, with poles reversed, and a keeper or armature across them at both ends. The term armature is also applied to the core and coil of the electro-magnet, which revolves before the poles of the permanent magnet in the magneto-electric machine, and to a part of the telegraph sounder.

Armed Neutral'ity, a term denoting the condition of affairs when a nation not only assumes a threatening position, but maintains an armed force to repel any aggression on the part of belligerent nations between which it is neutral. The term is applied in history to a coalition entered into by the northern powers in 1780 and again in 1800.

Armed Sol'dier of Democracy, a term occasionally applied to Napoleon Bonaparte because of his supposed expression of the ideals following the French Revolution.

Armenia, är-mē'nĭ-a, a mountainous region of western Asia with an area of about 120,000 square miles. It is now partitioned among Turkey, Persia, and Russia.

The plateau of which Armenia chiefly consists is mountainous and volcanic. The ridges, of which there are four principal, are generally parallel to each other, running, with sundry deviations, east and west, and between them are broad valleys and plateaux; that of the Aras, at Mount Ararat, being 2,890 feet, and many others 5,000 to 8,000 feet above the sea-level. The mountains are mainly composed of trachytic porphyry; with slate, limestone, etc., appearing on the sides of the chains, and sometimes rising up with the porphyry. Granite is also met with, but is not frequent; and in the north Tertiary fossiliferous rocks are found. Its volcanoes are all quiescent, unless we except Ararat, of which an eruption took place in 1840, accompanied by a disastrous earthquake. A few mountains, as Ararat, Alaghez, and Bangöldagh, rise above the line of perpetual snow, but this is not generally the case; and there are no passes but such as can be crossed in a single day. Silver, lead, iron, and copper are found in the mountains; and the last two have to some extent been wrought in modern times. Rock salt is plentiful, and is exported in considerable quantities to Persia and elsewhere. Mineral waters abound, but little or nothing is known of their qualities. Several important rivers take their rise in Armenia, namely the Kur or Cyrus, and its tributary the Aras or Araxes, flowing east to the Caspian Sea; the Akampsis or Tchorak, and the Halys or Kizil-Irmak, flowing north to the Black Sea; and the Tigris and Euphrates, which flow into the Persian Gulf. There are also several minor tributary streams. The only considerable lakes are those of Van, 70 miles in length and about 28 in breadth; Goukcha, Sevanga or Sevan northeast of Erivan, about 40 miles long by 15 broad; and Urumiyah.

The climate of Armenia is very severe, presenting a marked contrast to that of the warm regions of the Lower Euphrates, and to the mildness prevalent on the shores of the Black Sea. Winter in Armenia continues from October to May, spring and harvest a month each, and the change to the summer is very rapid. The heat, especially in the valleys, during summer, is great, and rain seldom falls. In Erivan, which is a degree of latitude south from Trebizond, the thermometer in winter falls 36° F. lower than it does in the latter; and in summer it rises 24° F. higher. On the plateaux of Erzeroom, Gumri, etc., the difference is still greater; indeed, in the town of Erzeroom the snow lies in the streets for eight months of the year. East and southeast winds in summer, west winds in spring and northeast storm winds in winter, are most prevalent. The soil of Armenia is reckoned on the whole productive, though in many places it would be quite barren were it not for the great care taken to irrigate it. Wheat, barley, tobacco, hemp, grapes, and cotton are raised; and in some of the valleys apricots, peaches, mulberries, and walnuts are grown. From the nature of the country the rearing of stock is carried on to a greater extent than agriculture. The horses are spirited, fleet, and fiery. Pines, birches, poplars, and beeches flourish, but there are no thick forests, except in the northern parts of the country. The flora is not so varied as might be expected in such an Alpine country; in several respects it resembles the vegetation of the Alps of Tyrol and Switzerland.

The inhabitants are chiefly of the genuine Armenian stock; but besides them, in consequence of the repeated subjugation of the country, various other races have obtained a footing. Of these the principal are the Turcomans, who still maintain their nomadic habits, and from whom the country has received the name of Turcomania. In the southern portion are the predatory Kurds and the Turks; on the Tchorak, Georgians; and throughout the whole country, Greeks, Jews, and Gypsies. The total

number of Armenians has been estimated at 2,000,000, of whom probably one half are in Armenia. The remainder, like the Jews, are scattered over various countries, and being strongly addicted to commerce, play an important part as merchants. They are found over all western Asia; about 200,000 are in Constantinople and its vicinity; numbers are in Russia, Hungary, and Italy; some in Africa and America; and a large number in India, chiefly in the great marts, Bombay, Madras, and Calcutta. Everywhere they are engaged in banking and trading. Their eyes and hair are black, their look lively, noses aquiline, and their complexion somewhat swarthy. The women are remarkable for the delicacy and regularity of their features. Like the Jews, whom in many respects they resemble, their ruling passion appears to be an inordinate love of gain, but they are generally esteemed honest. Their mental capacity is good, and those who are educated are distinguished by superior cultivation and refined manners; but the mass of the people inhabiting their native country, in consequence of centuries of neglect, are grossly ignorant and superstitious.

History.— The legendary history of Armenia begins with Haïk, son of Togarmah, the great-grandson of Noah, mentioned in Gen. x. 3. He is said to have taken refuge in Armenia from the tyranny of Belus, king of Babylon, who was slain in pursuit of him. The seventh king in descent from Haïk was killed in battle with Semiramis, and the country became tributary to Assyria. From Haïk the country derived the name Haikistan, and from Aram, his sixth successor, that of Armenia. Armenia continued subject to Assyria under its own princes till the revolt of the Medes and Babylonians against Sardanapalus, when Barbak, the king of Armenia, joined these powers and recovered his independence. Tigranes I. is said to have been the ally of Cyrus against Astyages, and to have built the city of Tigranocerta. His successor, Vhakin, the legendary hero of Armenia, was deified after his death. Vahi, the last of the dynasty of Haïk, was killed in fighting against Alexander as the ally or vassal of Darius. The duration of the dynasty was about 1,800 years. Armenia was now incorporated with the kingdom of Syria. It recovered its independence under Ardvates, 317 B.C., during the dissension among the successors of Alexander, but on his death submitted to the Seleucidæ. About 190 B.C. Artaxias and Zariadres, two Armenian nobles, freed themselves from the dominion of Antiochus the Great and established the kingdoms of Armenia Major and Armenia Minor. Armena Major was re-conquered from Artaxias II. by Antiochus Epiphanes. About 149 B.C. Mithridates, or Arsaces VI., king of Parthia, whose dominion extended over Media, Persia, and Babylonia, placed his brother Waghershag or Valarsaces on the throne of Armenia, and introduced the dynasty of the Arsacidæ into the country. He built cities and organized the defenses of the country. His great-grandson, Tigranes II., whose long reign appears to have begun about 96 B.C., conquered Artenes, king of Sophene or Armenia Minor, and united all Armenia under his sway. He was successful in war against the Parthians, and made himself master of the whole Syrian monarchy. He is also said to have founded or built Tigranocerta, the origin of which is likewise attributed to his probably mythical predecessor. Being the son-in-law of Mithridates, king of Pontus, while Mithridates was preparing to renew his war with the Romans after the death of Sulla he invaded Cappadocia at his instigation and carried away much spoil and many prisoners. Mithridates, after his defeat, took refuge with Tigranes, who does not seem to have been disposed to render him active assistance; but Lucullus made a peremptory demand through Appius Clodius for his surrender, which left Tigranes no alternative but a declaration of war, 69 B.C. Disregarding an invasion of Cilicia, Lucullus at once carried the war into Armenia, defeated the numerous forces of Tigranes, and captured Tigranocerta. Antiochus Eusebes was reinstated on the throne of Syria, and other dependents of Tigranes revolted. Tigranes in the meantime, with the assistance of Mithridates, collected another army which was again defeated by Lucullus. Favored by disaffection among the Roman troops, however, Tigranes recovered the greater part of Armenia, and defeated Fannius, the lieutenant of Lucullus. Pompey, who arrived in 66 B.C., after overthrowing Mithridates, who had also recovered his dominions, advanced to Armenia, which was at the same time invaded by the Parthians, instigated by the revolted son of Tigranes. The Parthians speedily withdrew, and young Tigranes fled to Pompey. At this critical juncture the elder Tigranes hastened to make his submission to the Roman general, who left him in possession of his kingdom, but deprived him of the provinces of Sophene and Gordyene, which he erected into a kingdom for the younger Tigranes. The elder Tigranes continued faithful to the Roman alliance, and Gordyene, which had been seized by the Parthians, was soon after restored to him. Tigranes died about 55 B.C. His son Artavasdes was made prisoner by Antony and carried to Egypt, where he was put to death by Cleopatra in 30 B.C. Armenia continued subject to the Romans, who appointed its princes from the family of the Arsacidæ till the time of Trajan, who made it a province. It was given up by Hadrian and again ruled by the Arsacidæ. Chosroes defended it during a long reign against the power of Persia, which had recently re-established its monarchy on the ruins of the Parthian empire; but about 258–259 A.D. Sapor, king of Persia, unable to subdue Chosroes by force of arms, caused him to be assassinated, and his son Tigranes being an infant, took possession of the country. Tigranes was restored by the Romans in 286, the third year of Diocletian. At the beginning of his reign he persecuted the Christians, who were numerous in Armenia, but was himself converted to Christianity, it is said, by Gregory the Illuminator. Armenia was thus the first country which officially embraced Christianity. On the defeat of Galerius by the Persians in 296 Tiridates, who fought valiantly as the ally of the Romans, was compelled to follow the retreat of his protectors; but the succeeding campaign restored him, and his dominions were extended in the peace with Persia which followed. By the treaty into which Jovian, the successor of Julius, entered with Sapor II. 363 A.D., the Romans were compelled to abandon the protection of Armenia. It was speedily reduced to a

Persian province, but after the death of Sapor its independence was restored in a new treaty of peace made with Theodosius in 384. The country, long oppressed by the contentions between the Romans and Persians, soon fell into division through the attraction of these rival powers. A Persian king or governor, Chosroes, was set up over the eastern, and a Roman, Arsaces, over the western portion of the country, both being of the royal house of Armenia. On the death of Arsaces the Romans suppressed the form of royalty, and annexed their portion of the country to the empire under the military command of a count of the Armenian frontier. This occurred in the reign of Theodosius II. On the death of Artasires or Ardashir, the successor of Chosroes, Bahram V. of Persia (about 431) annexed the Persian portion under the name of Persarmenia. The Persians exerted themselves to extirpate Christianity, but failed to do so; and on the fall of the Sassanidæ (632) the country was united again under the Greek empire. It now became the scene of incessant struggles between the declining empire and the rising Mohammedan power, and as it was persecuted by the emperors for its adoption of the Monophysite heresy its sympathies were not always with the former. The dynasty of the Pagratids or Bagratidæ was established by the arms and influence of the caliphs. It was a family of Jewish origin and appears to have risen gradually to influence in the country. The date of its elevation to royalty is usually given as 885, but a much earlier date is sometimes assigned. It lasted till 1079, when the country again became dependent on the Greek empire. During this period several other dynasties which it is not necessary specifically to notice reigned simultaneously in different parts of the country. On the fall of the Pagratidæ a relative of the last king founded a small kingdom in the north of Cilicia, which gradually extended to the Mediterranean, and was known as Lesser Armenia. It was overthrown by the Mamelukes in 1375. Armenia formed part of the empires of Genghis Khan and Tamerlane, and a great part of it was conquered by Selim II. in 1522. Henceforth it was shared between the Turks and Persians, the former having the greater part of it. In 1828 Russia obtained a considerable portion of it, and this was greatly augmented by the treaty of Berlin (1878). Russian Armenia includes the governments of Erivan and Elizabethpol, the territory of Kars, etc., with the important towns of Tiflis, Kars, and Erivan. At the time of the Berlin treaty Turkey made promises of better treatment for her Armenian subjects, but these have been disregarded and in 1895–6 many thousands of the Armenians in different localities were massacred and atrocious cruelties perpetrated upon them by the Turks, with full approval, it would seem, of the Sultan and his advisers.

Art.— The only important ruins of the Roman period are at Karni. After the country had become Christian many churches were built, possessing much architectural character. The most interesting of these is the cathedral at Ani, built about 1010, while of nearly equal importance is the cathedral of Kiutas, on the basilican plan. A church with a striking dome and five naves is found at Mowki, and there are many others remarkable for the delicacy of decorative details. The most richly ornamented of these is that at Mtzkhet in Georgia. The Armenian architects and artists were much given to the employment of decorative inscriptions, as were their Mohammedan neighbors. Carving in wood and ivory were much practised, but the Armenians especially excelled in the production of cloisonné enamel and in the employment of geometric ornament applied to buildings as well as to small objects, such as the sacred vessels of the church and toilet articles. Wall painting was also an Armenian accomplishment and one in which not a little independence of Byzantine influence was exhibited.

Armenian Church.— The Armenians received Christianity as early as the 3d century. During the Monophysitic disputes, being dissatisfied with the decisions of the Council of Chalcedon (451), they separated from the Greek Church in the year 536. The Popes have at different times attempted to gain them over to the Roman Catholic faith, but have not been able to unite them permanently and generally with the Roman Church. There are, however, at present, about 100,000 United Armenians who acknowledge the spiritual supremacy of the Pope; they agree in their doctrines with the Catholics, but retain their peculiar ceremonies and discipline. At different times force has been used to make them conform to the religion of Mohammed; but the far greater part are yet Monophysites, and have remained faithful to their old religion and worship. Their doctrine differs from the orthodox chiefly in their admitting only one nature in Christ, and believing the Holy Spirit to issue from the Father alone. In their seven sacraments, which they call mysteries, there are these peculiarities, that in baptism they sprinkle thrice and dip thrice, and this is immediately followed by confirmation; that in the Lord's Supper they mix no water with the wine, and use leavened bread, which they distribute dipped in wine; and that they allow extreme unction only to divines immediately after their death. They adore saints and their images, but do not believe in purgatory. In fasting they surpass the Greeks. Their feasts are fewer than those of the Greeks, but they celebrate them more devoutly. They worship, in Turkey, mostly in the night time; the mass is said in the ancient Armenian, the sermon is preached in the modern. Their hierarchy differs little from that of the Greeks. The *catholicus* or head of the Church has his seat at Etchmiadzin, a monastery near Erivan, the capital of the Russian Armenia, on Mount Ararat. The holy oil, which he prepares and sells to the clergy, and the frequent pilgrimages of the Armenians to Etchmiadzin, supply him with means for the support of a magnificent style of worship and of establishments for education. He maintains in his residence a seminary for the education of divines. There is here also a printing press. The patriarchs, bishops, and archbishops of the Armenians are invested by him, and every three years confirmed in their offices or recalled. The remainder of the clergy resemble the priests of the orthodox church in rank and duties. The monks follow the rule of St. Basil. The *vartabets,* who live like monks, cultivate the sciences, take degrees, which may be compared with the usual academical honors, and are the vicars of the bishops, form a class of divines peculiar to

the Armenian Church. The secular priests must be married once, but are not allowed to take a second wife. Both monks and clergy in general are ignorant and superstitious. Armenian churches have been established in the United States wherever a considerable body of Armenian refugees have settled.

Language and Literature.— The Armenian language belongs to the great Indo-European family of languages, and is most closely connected with the Iranic group. The Old Armenian or Haikan language, which is still the literary and ecclesiastical language, is distinguished from the New Armenian, the ordinary spoken language, which contains a large intermixture of Persian and Turkish elements. The most learned Armenian antiquaries do not pretend to trace their literature further back than about 150 years before the Christian era, when Marabas Catina wrote a history of Armenia, and earned for himself the title of the Armenian Herodotus. He was followed by some half dozen historians and mythologists, but all these early productions are lost, though they have not been quite valueless, inasmuch as they were the sources whence later Armenian writers compiled works still extant. The authors who lived in the 4th century of the Christian era are the first whose writings have been preserved. Christianity then prevailed in Armenia, and her authors were princes and prelates. The 5th century was the golden age of Haikan literature. This century was fruitful in authors, and was further distinguished by two events important to the progress of learning. The Armenians till then had had no alphabet of their own, indifferently using Greek, Syriac, and Persian characters. Early in the 5th century Mesrop Masdoty invented a Haikan alphabet of 38 letters, still called, in honor of the inventor, Mesropian, and now employed as capitals, since others of more convenient form have supplanted them in common use. About the same time schools were instituted throughout Armenia, and the scholars there trained exerted themselves in producing Haiken versions of the Bible, and of the masterpieces of Greece and Rome. One of the most distinguished authors who now appeared was Archbishop Moses Chorenensis or Chorenabyi. Besides innumerable translations, he wrote a history of Armenia, a treatise on rhetoric, and a treatise on geography — all of which, together with some homilies, have been preserved, as well as some hymns still habitually sung in the Armenian Church service. His 'History of Armenia' was published in 1736, with a Latin translation, by the celebrated W. Whiston and his son George. In the 6th century Haikan literature first remained stationary, and then began to decline. This decline continued down to the 16th century. During this period authors abounded, but in a literary sense their productions were worthless. A few histories, however, national, Tartar, Arab, etc., some of them in verse, deserve esteem for the information they contain. In the 17th century Armenian schools and colleges arose in the East and in the West, Armenian printing presses were set up in various towns, and Armenian literature began to revive. In the 18th century the revival was complete, very much owing to the zealous and judicious exertions of Petro Mechitar, a Catholic Armenian, who in 1701 founded a religious society at Constantinople for the purpose of elevating the Armenians by diffusing among them a knowledge of their ancient literature and language. Being persecuted by the opposite sect he fled with his adherents to the Morea, then under the Venetians, and established a monastery and academy at Modon. The Morea reverting to the Ottoman sceptre, Mechitar transferred his institution to the small island of San Lazaro at Venice, where it has ever since remained and prospered. Abbot Mechitar, during the remainder of his life (he died in 1749) successfully exerted himself to render his monastic college the chief seat of Armenian erudition and education. The best Armenian press extant is the Mechitarist, from which issues a newspaper that circulates widely in the Levant. Here many of the classical works of England, France, Italy, and Germany have been translated into Armenian. There is also a Mechitarist college in Vienna, and a branch in Munich. Wherever any extensive community of Armenians have settled they have set up a printing press, as in Amsterdam, Leghorn, Moscow, Venice, Astrakhan, Constantinople, Smyrna, Tiflis, St. Petersburg, Madras, Calcutta, etc., and at several of these places periodicals are published. The best Armenian dictionaries for foreigners are the Armenian-French one published at Venice in 1812; the Armenian-Italian of Emmanuel Tchaktchak (Venice 1837); the Armenian-English of Aucher as improved by Bedrossian (Venice 1868–79); both Armenian-English and English-Armenian); and the French-Armenian of Norayr (Constantinople 1884).

Bibliography.— Creagh, 'Armenians, Koords and Turks'; Gladstone, 'The Armenian Question'; Greene, 'The Armenian Crisis and the Rule of the Turk'; Gregor, 'History of Armenia'; Norman, 'Armenia'; Lynch, 'Armenia'; Nazarbek, 'Armenian Revolutionists upon Armenian Problems'; Vartooguian, 'Armenia's Ordeal'; Hanrachod, 'Chronological Succession of the Armenian Patriarchs'; 'Life and Times of St. Gregory, the Illuminator'; Bedrossian, 'New Armenian Dictionary'; Msériantz, 'Studies on Armenian Dialectology.'

Armentieres, är'mäṅ'tyâr' (Latin, *Armentaria*), a town in France, on the Belgian frontier, 10 miles west-northwest of Lille, on the Lys. The town has a communal college and factories for spinning flax, hemp, and cotton yarn. There are also manufactories of woolen cloth, table linen, calicoes, lace, thread, beetroot sugar, and tobacco; bleachfields, distilleries, soap-works, tanneries, and salt-refineries, with a considerable trade in grain, brandy, iron, tobacco, soap, etc. Bricks are made in the neighborhood in large quantities. Pop. (1901) 29,401.

Arm'felt, Gustav Moritz, Count of, a Swedish soldier: b. 1757; d. 1814. Though he had been highly favored by Gustavus III., he incurred the enmity of the Duke of Sudermania, guardian to the young king, Gustavus IV., and was deprived of all his titles and possessions. He was restored to his fortune and honors in 1799, when Gustavus IV. attained his majority,

and held several high military posts. Subsequently entering the Russian service, he was made count, chancellor of the University of Åbo, president of the department for the affairs of Finland, member of the Russian Senate, and served in the campaign against Napoleon in 1812.

Armida, är-mē'dȧ, the beautiful enchantress in Tasso's 'Jerusalem Delivered.' She succeeds in bringing the hero Rinaldo to her enchanted gardens, where he forgets his vows for a time. Messengers from the Christian host having arrived, Rinaldo escapes with them by means of a powerful talisman. In the sequel Armida becomes a Christian.

Armies. See ARMY.

Ar'millary Sphere (L. *armilla*, a hoop), an astronomical instrument composed of a series of rings, all circles of one sphere, intended to represent the principal circles of the celestial globe, the rings standing for the meridian of the station, the ecliptic, the tropics, the Arctic and Antarctic Circles, etc., in their relative positions. Its purpose is to represent the apparent motions of the solar system.

Arminianism, a term applied to a certain phase of Protestant theology. In the Netherlands early in the 17th century there was a revolt against the doctrine of unconditional election as taught by the rigid Calvinists. The most important person, though not the first one, in this revolt was James Arminius (q.v.). A controversy was carried on between him and Gomarus over the question of predestination, and, after the death of Arminius, with increased vigor by their followers. In 1610 the Arminians set forth their views in a 'Remonstrance' covering the points in controversy which in substance was as follows:

(1) God decreed to save through Christ those who believe in his Son and who persevere in faith and obedience through life, but he leaves in sin those who are not believers. (2) Christ died for all, but no one except the believer has remission of sins. (3) Man can neither do nor think anything truly good until he is born again through the Holy Spirit. (4) All good in the regenerate man is brought about by the grace of God, but this grace is not irresistible. (5) Those who are truly converted have power given them through the Holy Spirit and the help of Christ, so that if they desire his aid and are not inactive, no power can take them away from Christ.

In 1618 the Synod of Dort met and condemned the five articles, and many of the remonstrant ministers were deposed, but in 1630 they were granted religious liberty. They have continued to the present as one of the smaller religious sects of Holland with a presbyterial organization and a theological seminary at Amsterdam. The present importance of Arminianism is due to the fact that the founders of Methodism (q.v.) incorporated into their system the teachings of Arminius and his immediate followers. This is the belief of the Methodist Church to-day, as well as that of many individuals belonging to churches nominally Calvinistic.

Armin'ius, a German chief celebrated by his fellow-countrymen as their deliverer from the Roman yoke: b. about 18 B.C.; assassinated A.D. 19. Sent as a hostage to Rome he served in the Roman army, and was raised to the rank of *eques*. Finding on his return to Germany that the Roman governor, Quintilius Varus, was making efforts to Romanize the German tribes near the Rhine, he placed himself at the head of the discontented tribes and completely annihilated the army of Varus, consisting of three legions, in a three days' battle fought in the Teutoberg forest. After many years' resistance to Rome he drew upon himself the hatred of his countrymen by aiming at the regal authority, and was assassinated. A national monument to his memory was erected on the Grotenburg, near Detmold, in 1875.

Armin'ius, Jacobus, the founder of Arminianism (q.v.): b. Oudewater, Holland, in 1560; d. in 1609. He early showed marked promise as a scholar, and entered the University of Leyden at the age of 15. His ability was so apparent that certain officials of Amsterdam undertook the expense of his education for the service of the Church. This enabled him to study at Geneva, where Beza was at the height of his influence and by whom Arminius was greatly influenced. He also studied at Basel and Padua and visited Rome. Returning to Holland he was ordained in 1588 and became pastor of the Reformed Church at Amsterdam. At that time he was a rigid Calvinist, but milder views of predestination than those which he had learned from Beza having made their way into Holland, Arminius was called upon for a defense of Calvinism. He made a more careful examination of the disputed points and as a result modified his own views, though still holding to predestination. In spite of the opposition which arose because of his changed opinions he was offered and accepted a professorship in the University of Leyden in 1603. A controversy soon broke out between him and his colleague, Gomarus, a zealous and extreme Calvinist. Two parties were formed in and beyond the university, and the controversy was kept up till his death in 1609. See ARMINIANISM.

Ar'mistead, George, an American soldier: b. in New Market, Va., about 1780; d. in 1818. He entered the United States army in 1799, became a major in 1813, and distinguished himself for bravery at the capture of Fort George in Canada in 1813 and the defense of Fort McHenry near Baltimore the next year.

Ar'mistice, a suspension of hostilities between two belligerent powers or two armies by mutual agreement. It may either be for a definite period or until its termination is proclaimed. An armistice throughout the whole theatre of war can be concluded only by the belligerent governments, and does not take full effect until it has been ratified. A partial armistice may, however, be concluded by the commanders of individual armies or army corps, and such an armistice requires no ratification, although it may be disapproved and abolished by the government. An armistice is often concluded for only a few hours to bury the slain, remove the wounded, and exchange prisoners, as also sometimes to allow of a parley between the opposing generals. A breach of an armistice is regarded as a violation of the law of nations. Sometimes a regular armistice is pre-

ceded by an actual suspension of hostilities. If the conditions on which an armistice was agreed upon, as that while it lasted all preparations for attack or defense should cease, are violated by either side, the enemy is entitled to resume hostilities at once. A general armistice is usually the preliminary of a peace, and can only be proclaimed by the commanders-in-chief or their home governments.

Ar'mitage, Edward, an English historical and mural painter: b. London, 20 May 1817; d. in 1896. He studied in Paris, where, in 1842, he exhibited his first independent work. In the following year his 'Landing of Cæsar' gained a prize of $1,500 in London; and in 1845 and 1847 he carried off prizes of $1,000 and $2,500. He was made a fellow of the Royal Academy in 1872, and in 1875 was appointed lecturer on painting there. His mural paintings include a series of noble figures of Christ and the 12 apostles, executed for Saint John's Roman Catholic Church in London.

Ar'mitage, Thomas, an American clergyman: b. Pontefract, England, 2 Aug. 1819; d. Yonkers, N. Y., 20 Jan. 1896. He prepared himself for the ministry and preached his first sermon when 16 years old. Coming to New York city in 1838, he was actively engaged in the ministry of the Methodist Church until 1848, when he became a Baptist, and was pastor of the Norfolk Street Church (later the Fifth Avenue Baptist Church). In 1890 he was made pastor emeritus, given a residence in Yonkers. He was one of the founders of the American Bible Union. He published 'Jesus: His Self-Introspection' (1878); 'Lectures on Preaching' (1880); 'History of the Baptists' (1886).

Ar'mor. See ARMS AND ARMOR.

Armorclads. See WARSHIPS.

Ar'mor-plate, in modern usage, a metallic covering for ships or fortifications, intended to furnish protection against gun-fire. John Stevens of Hoboken, N. J., is universally credited with having originated the idea of applying armor to the sides of ships, he having designed a vessel with battery protected by inclined armor and submitted her plans to the United States government during the War of 1812; but it was the development of the naval shell gun which led to the actual use of armor. The annihilation of the Turkish fleet at Linope in 1853 first drew general attention to the necessity of providing some protection against explosive shell, and the incident was soon followed by the construction of armored ships in the United States, France, and England. The "Stevens Battery," a steam, armored war vessel, was begun in the United States in 1854, a few months earlier than the first ironclad was laid down in Europe, but the French were the first to complete their vessels, and on 17 Oct. 1855, the Devastation, Love, and Tounante, the first ironclad squadron ever seen, after a close engagement of four hours, silenced the Russian forts at Kinburn, which had previously held the combined fleets of France and England at bay. No sooner, however, had the first thin iron plates proved themselves an effective shield against gun-fire, than the introduction of new and more powerful guns forced a corresponding development in the thickness and quality of armor. The progress of the contest is shown by the facts that, while in 1863 4½-inch iron plating made a ship invulnerable, in 1868 9-inch plating was required to the same end, and in 1872 a 12-inch plate was pierced on the firing ground. With the production of 12-inch plates the limit of regularity in manufacture with wrought iron seemed to be reached, and the cost of the plate upon plate system, owing to the difficulty of making the plates fit each other, led to the use of the sandwich system, in which layers of wood separated layers of iron plating. The advent of the Krupp 14½-inch rifle and of the Woolwich 81-ton gun marked the final supremacy of the gun. Wrought iron armor had then reached its highest development on the British ship Inflexible, which was protected by two layers of 12-inch plates with 11 inches of teak between them and backed by 6 inches of teak and two 1-inch skin plates. Compound armor, composed of a hard steel face welded upon a wrought iron back, next came into general use, but homogeneous steel, first made in the form of heavy plating by Schneider & Co. of France, disputed with it for the palm and finally proved its superiority. In 1890 nickel steel had its first public trial, on the United States naval proving ground at Annapolis, Md., in competition with compound armor and with homogeneous steel; and in the same year a steel plate hardened on one face was also tried at Annapolis and showed phenomenal resistance to perforation. Further tests demonstrated the decisive superiority of the surface-hardened steel plates, called Harveyized from the inventor of the process, and in a very short time they were universally adopted for armoring ships. The following briefly describes the method of manufacturing this armor. The ingot, of approximately rectangular cross section and about twice the weight of the finished plate, is made of open-hearth steel, sufficient nickel being added to the furnace charge to give about 3¼ per cent in the casting. After cooling, the ingot is stripped, reheated, and forged to nearly the required thickness, being handled by a porter bar forged from the upper end, and the entire forging operation usually requiring several heats. In the early days of steel armor manufacture immense steam hammers were used for forging, but now hydraulic presses are preferred. After forging, the upper end of the plate is cut off under the hammer or press, and the remainder, after cooling, placed in the Harveyizing furnace with its back and sides well protected by refractory materials and its face covered with a carbonizing mixture, where it is raised to a high temperature and left to soak for several days. When the carbon has penetrated sufficiently into its face, the plate is removed from the furnace and given a secondary forging which reduces it to the required thickness, after which it is trimmed to size in a planer and its face is cleaned. The next operation consists of heating the plate and chilling its surface with a spray of cold water, which hardens the highly carbonized face but leaves the body of the plate still soft. If the plate is to be bent or curved this operation is performed under a press after the carbonizing but before the final heating for hardening the face. The final operation is boring and tapping the bolt holes in the back of the plate. If holes are required for structural purposes in the hard

face of a plate, it is softened at the proper places by means of an electric current, since otherwise it will resist any tool. Within the last few years improvements upon the Harvey process have been developed by Krupp at Essen, and the Krupp process is now widely used. The details are kept secret, but it is probable that the essential feature is the use of chrome as well as nickel in the steel, this alloy permitting the chill to be carried deeper into the plate than when steel containing nickel only is used. The supercarbonization, though brought about by the use of a hydrocarbon gas, is the equivalent of ordinary cementation, and the usual cold spray is used to chill the surface. Kruppized plates offer some 20 per cent more resistance to ordinary armor-piercing projectiles than Harveyized plates, but when attacked by the capped projectiles now coming into general use the gain in resistance is much less. Their freedom from cracking is a further point of superiority. The armor applied to the protection of ships is also used on coast and frontier defenses, but another armor, ill adapted to naval use on account of its weight, has also been developed. Chilled cast iron was first tested as armor in Prussia in 1868, and then and in many subsequent trials showed remarkable resistance to gun-fire. The Grason system, in which ellipsoidal-shaped turrets are built up of very heavy iron castings, chilled on the outer surface, and fitted together without bolts, has been largely used for land fortifications in Europe.

Backing and Fastenings.— Armor was first applied to wooden ships, and when iron and steel ships succeeded these it was found necessary to interpose wood between the skin-plating of the ship and the armor to provide a surface which could be trimmed to fit the latter, and to decrease the injury caused to the ship's side by the impact of shot. East India teak is used for armor backing, but the modern tendency is to reduce its thickness as far as is practicable, and even to dispense with it entirely in above-water structures. Through bolts were first used for fastening armor to ships, but they caused leaks, besides weakening the armor, and the bolts now used only screw a short distance into the backs of the plates, being set up with nuts on their inner ends. They are made of forged steel; have shanks of reduced diameter to prevent breaking at the threads; have packing to prevent leakage around them; and usually have rubber washers under their nut heads. One bolt is used to about every 4½ square feet of plating, and their diameters are from 1½ to 3½ inches according to the thickness of the armor.

Disposition and Uses.— When sea-going armored ships first began to be built it was possible to completely cover them with armor then impenetrable, but the increasing power of guns soon made it necessary to restrict the defended area if it was to be given complete protection. In the hopeless attempt to secure invulnerability armor was gradually stripped from other portions and concentrated over parts considered vital. The restriction of batteries to a few heavy guns, mounted in turrets or a central citadel, allowed the thickness of armor protecting men and guns to be greatly increased, with a corresponding reduction in its extent, and at the same time water-line armor was made thicker and thicker and of less and less area. Of late years, however, there has been a growing tendency to return to the early practice of expanding armor over a large area. Great as are the displacements of modern battleships it is not deemed wise to attempt to secure complete protection for any one portion of them; it is recognized that armor can only be expected to furnish a reasonable amount of security to what it covers; to keep out all small projectiles; and above all to keep out explosive shell with large bursting charges, compelling resort to armor-piercing shell. Modern battleships often carry as much as 4,000 tons weight of armor. The principle of inclining armor so as to cause it to deflect projectiles is largely used in protective decks covering the propelling machinery, and also to some extent in shields for the defense of guns' crews. Hard-faced armor plates of as great weight as 50 tons and of as great thickness as 18 inches have been applied to ships, but in the best present practice a thickness of 12 inches is seldom exceeded. A width of about 9 feet and a length of about 18 feet are the limiting sizes of armor plates now made. Modern naval guns, firing capped projectiles, will more than overmatch the best armor plate, of thicknesses equal to their respective calibres, up to 3,000 yards' distance, provided the impact be normal to the plate's surface, but the fact that in actual battle most impacts will be at some inclination to the surface struck adds greatly to the real value of armor. There are two great plants in the United States for the manufacture of armor — the Bethlehem Steel Co. at Bethlehem, Pa., and the Carnegie Steel Co. at Pittsburg. The greatest foreign plants are at Sheffield, England, at the Creusot and the St. Chamoud works in France, and at Krupp's works in Germany.

PHILIP R. ALGER,
U. S. Naval Academy, Annapolis.

Ar'mored Train, a modern instrument of war severely tested in the American operations against Filipino insurgents in 1898–99, and in those of the British against the Boers in 1899–1900. Credit has been given to Admiral Fisher of the British navy for the first use of the armored train in war, when, in 1882, he covered a locomotive with boiler plate and equipped cars, similarly protected, with field guns and put them to effective practical use. But the germ of the idea was of earlier date. When the Germans invested Paris, the French made frequent sorties from the city, and in many of these attacks were assisted by field guns mounted on wagons and carriages. Later they were mounted on railroad cars, which were protected in their vital points against the enemy's guns. Since 1882 most of the military powers of Europe have been experimenting in this direction and Great Britain has now probably the most complete and efficient armored trains in the world. The best that the British army possesses is the engine and train of the First Sussex Artillery Volunteers. The model design was made from special designs for war purposes. The protected engine carries a Maxim gun, and the protected cars have heavy field guns, operated by machinery, so that any part of the surrounding country can quickly be covered. Arrangements are made to compensate for the recoil, and also to give steadiness and stability to the cars. This latter is accomplished by an arrangement

for clamping the truck to the rails by strong screw clips whenever the gun is fired. There are also several steel-plated vans accompanying the train, in which horses and soldiers can be safely conveyed. This type of movable fortress performed notable achievements in South Africa, and in the sorties from Ladysmith and Kimberley was the chief implement that forced the Boers back. With machine guns and field pieces the moving train becomes a valuable offensive apparatus, being able to move up close to the enemy's lines or retreat to a point beyond the range of small arms. The rapidity with which the train can change its base of action renders it a difficult object for the batteries of an enemy to hit, and almost the only way to defeat its operations is to wreck or derail it; it then becomes a helpless target for long-range guns. Probably the first attempt in the United States to provide an armored car was that made by the Michigan Central Railroad Company, on the order of the American Express Company, for the purpose of protecting the valuable articles carried on its special express trains. These armored or «arsenal cars» were so constructed as to make the centre of them with its steel plating a thoroughly bullet-proof room, with apertures so disposed as to enable the guards within to resist an attack by thieves from any quarter. During the remarkable dash of the American troops in the Philippines into the northern part of the island of Luzon, in search of the fugitive insurgent leader Aguinaldo, in 1899, much effective work was accomplished by an improvised armored train.

Ar'morer, a term formerly applied to a maker of arms and armor, a very important handicraftsman in the Middle Ages and down to the end of the 16th century and even later. (See ARMS AND ARMOR.) At the present day the term denotes persons employed to keep the arms of the soldiers in repair, or the custodian of an armory. On board a man-of-war the armorer is a petty officer appointed to keep the small arms in complete condition for service.

Armor'ica, the country of the Armorici. The name was formed from two Celtic words signifying «upon the sea,» and was apparently applied in ancient times to the whole northern and western coast of Gaul. It was afterward confined to the province of Brittany.

Ar'mory, a building, or military station appropriated to the storage of arms, or the use of troops. In the United States the term is generally applied to the headquarters of the local militia, and signifies almost the equivalent of a club house, to which is added a drill shed, for military manœuvres.

Ar'mour, Herman Ossian, an American merchant: b. Stockbridge, N. Y., in 1837. After several years spent in the grain commission business in Chicago he became in 1865 the New York representative of the Milwaukee packing firm of Armour, Plankinton & Co., which retained the firm name of H. O. Armour & Co. until 1870. The name was then altered to Armour & Co., which is now the most important provision firm in the world.

Ar'mour, Philip Danforth, an American philanthropist: b. Stockbridge, N. Y., 16 May 1832; d. 6 Jan. 1901. He was a miner in California in 1852–56, but engaged in the commission business in Milwaukee in 1856–63; and later became the head of the pork packing firm of Armour, Plankinton & Co., Chicago. He founded the Armour Mission and the Armour Institute of Technology (q.v.), both in Chicago; the former at a cost of about $250,000, and the latter with an endowment of $1,500,000, subsequently increased.

Ar'mour Institute of Technology, an American co-educational institution, founded in Chicago, Ill., by Philip D. Armour, in 1893. Its scheme includes (1) The Technical College; (2) The Department of Commercial Tests; (3) The Armour Scientific Academy. The institution had 666 students in 1901 and 38 professors in its faculty. Its property was valued at $4,560,000.

Arms and Armor. The earliest arms were everywhere made of stone. Stone was succeeded by bronze in the manufacture of weapons of war. The commonest warlike relics of the bronze age that have come down to us are daggers and spear-heads. From the descriptions of Homer we know that almost all the Grecian armor, defensive and offensive, in his time was of bronze, although it is evident that iron was sometimes used in the time of Homer for making weapons, from the fact that he occasionally uses the Greek word for iron (*sidēros*) for a sword. Not the sword, however, but the lance, spear, and javelin, were the principal weapons of this age among the Greeks. The bow is not often mentioned, although a bow belonging to Pandarus is described in the Iliad, and in the Odyssey Ulysses is represented as very expert in the use of this weapon. Among the most ancient nations the Egyptians seem to have been most accustomed to the use of the bow, which was the principal weapon of the Egyptian infantry. The Egyptian bow was somewhat shorter than the height of a man; the arrow was usually made of reed, the head of bronze, but sometimes of flint. Peculiar to the Egyptians was a defensive weapon the object of which was to catch and break the sword of the enemy. With the Assyrians also the bow was a favorite weapon; but with them lances, spears, and javelins were in more common use than with the Egyptians. Most of the large engines of war, chariots with scythes projecting at each side from the axle, catapults, and ballistæ, seem to have been of Assyrian origin. All of those mentioned can at any rate be traced back to the Assyrians, to whom the invention of the catapult and the ballista was attributed by classical writers. During the historical age of Greece the characteristic weapon was a heavy spear from 21 to 24 feet in length. The sword used by the Greeks was short, and was worn on the right side. The Roman sword was of Spanish origin, from 22 to 24 inches in length, straight, two-edged, and obtusely pointed, and as by the Greeks was worn on the right side. It was used principally as a stabbing weapon. On the Trajan column, belonging to 114 A.D., the sword appears considerably longer than that used at an earlier period. The Roman sword was originally of bronze, but like all other offensive weapons among the Romans was always of iron in the time of Polybius (2d century B.C.), when bronze continued in use only for defensive armor. The characteristic weapon of the Roman soldier was the pilum, a kind of

pike or javelin, about 5 or 6 feet in length, with a wooden shaft and an iron head, the latter of which was about one third of the length of the whole. The pilum was sometimes used at close quarters both as an offensive weapon and as a means of parrying blows, but more commonly it was thrown along with the other javelin, which every Roman spearman (hastarius) carried when within 10 or 15 paces of the enemy. The pilum, when thrown from this distance, would fix itself in the enemy's shield, whereupon the Romans would rush up, and seizing hold of the shafts of their pila draw down the shields in which they were fixed, and follow up the attack with their swords. In addition to the large engines of war that have been already mentioned as of Assyrian origin (scythe-chariots, catapults, and ballistæ) the Romans made use of battering-rams for making breaches in the walls of fortified places. The Greeks are said to have used a sort of cannon made on the principle of the modern air-gun. The Romans also employed caltrops to embarrass the movements of an enemy's cavalry.

The principal pieces of defensive armor used by the ancients were shields, helmets, cuirasses, and greaves. No shields were carried by the Egyptian archers; but the Egyptian spearmen had large shields, rectangular below and semicircular at the top, and with a round sight-hole in this semicircular part. In the heroic age of Greece the shield is described as of immense size, so as to be capable of defending the whole body. In the early monuments the shield is still large, though not so large as it appears to have been in the heroic age. In shape it is round or oval, with a very considerable degree of convexity. At the time of the Peloponnesian war a still smaller shield came into use. The Romans had two sorts of shields — the *scutum,* a large, oblong, rectangular, highly convex shield, carried by the legionaries — and the *parma,* a small, round or oval, flat shield, carried by the light-armed troops and the cavalry. In the declining days of Rome the shields became larger and more varied in form. The helmet was a characteristic piece of armor among the Assyrians, Greeks, Etruscans, and Romans. Like all other body armor it was usually made of bronze. The Assyrian helmet was frequently conical. Sometimes it had the form of a truncated cone, and sometimes the pointed extremity was curved forward. The helmet of the historical age of Greece was distinguished by its lofty crest, which tapered downward to the back of the neck. The Etruscan helmet was also very high crested and sometimes had a wing rising to a considerable height on either side from points near the summit. The Roman helmet in the time of the early emperors fitted close to the head and had a hollow neck-guard and hinged cheek-pieces fastened under the chin, and a small bar across the face for a visor. The neck-guard and cheek-pieces were not peculiar to the Roman helmet, but were in common use wherever the helmet was worn. In later days the helmet of the Romans had a higher crown than that of the early emperors. The cuirasses of the Assyrians were close-fitting tunics made of several layers of flax plaited or interwoven and glued together. This kind of cuirass was introduced into Greece during the Peloponnesian war and was sometimes used even by the Romans. Before the Peloponnesian war the Greeks had the upper part of their body defended by bronze cuirasses. The defensive body armor of the Egyptian archers consisted of a quilted coat. The Egyptian spearmen had cuirasses of bronze scales or quilted with bands of metal. Under the Roman republic all the legionaries wore a bronze cuirass, consisting of a breast and back plate, with a border of pendent leather straps defending the lower part of the body. On the columns of Trajan and Antonine this cuirass is given only to officers, the legionaries wearing at that period only leather or linen cuirasses, on which circular plates of metal and metal shoulder-pieces were sewed, and to the lower border of which were attached oblong plates which served the purpose of the leather straps of the other cuirass. In the time of Trajan and Septimius Severus a flexible cuirass was added to the equipment of the Roman knight or horseman. This was made either of scales (*lorica squamata*) or of chains (*lorica hamata*). One of the latter kind has been found at Avenches in Switzerland, and is there exhibited. Greaves do not seem to have been worn by any of the eastern nations except the Persians, whose defensive armor resembled pretty closely that of the Middle Ages. The greaves of the Greeks (*knēmides*) were made in two pieces which were fastened together by clasps. The Roman greaves (*ocreæ*) were made in one piece and were often worn only on one leg. The Samnite practice was to wear the greave upon the left leg, which is the leg advanced in fighting with a shield on the left arm; but Vegetius mentions that the greave was worn by the Roman legionaries upon the right leg. The greave reached only from the knee to the ankle. The Roman soldiers had their feet protected by shoes set with nails (*caligæ*).

The favorite weapons of the Germanic races, by which the ancient civilization of Rome was to a large extent overthrown, were the battle-axe, the lance or dart, and the sword. Their defensive armor consisted almost exclusively of a shield made of plaited osier covered with leather and generally 8 feet by 2 in size. Afterward it was made round and bound with iron, and had several prominent bosses on its surface. The Frankish form of the German battle-axe was called *francisca* (francisque), and was the characteristic weapon of that tribe. It had a broad single-edged blade and a short haft, and was often used as a missile. The lance or dart of the Franks, called *angon,* closely resembled and was used exactly in the same way as the Roman pilum. The sword among the Franks was only a horseman's weapon. The shield of the Franks was round. Hardly any body armor (scarcely even a helmet) was used by them until the Carlovingian days. Swords belonging to the early iron age in Scandinavia are frequently found in the mosses of Schleswig. They are long, straight, two-edged, and often richly damascened. Shields belonging to the same district and epoch were made of wood, and were flat, round, and from 22½ to 44 inches in diameter. They were bossed and otherwise mounted, generally in bronze, sometimes in iron. The common arms of the Anglo-Saxon infantry were a spear, an axe, and a scramasax (a heavy single-edged knife). With the Anglo-Saxons as with the Franks the sword was especially a horse-

ARMOR.

1. French Foot Soldier, Eighth Century.
2. Polish Knight, end of Fifteenth Century.
3. French Soldier, about 1120 A. D.
4. Battle of Askalon (1099) from a Window in the Church of St. Louis, Paris.

5-6. German Full Armor, of the time of Maximilian I.
A. Mottled or Striped Armor. B. Ringed Armor. C. Fettered Armor. D. Shield Ornament. E. Plate Armor. F. Chain Armor.

13. Shield of time of Henry II. of France.

14–15. Battle Axes of Sixteenth Century.

man's weapon, being carried by none under the rank of thane. The sword carried by them was 3 feet long, broad in the blade, and round at the point. The Saxon shield was round or oval, made of wood covered with leather, and furnished with a high conical boss.

The arms and armor both of the Normans and Anglo-Saxons, but especially of the former, at the time of the Norman conquest of England are pretty fully illustrated by the Bayeux tapestry. On this work the horsemen appear armed with long lances as well as swords. The Normans are represented as well furnished with archers and cavalry, of which arms the Saxons do not seem to have had any. Maces, clubs, axes with shafts from 4 to 5 feet long, are seen in the hands of both. The shields are long, rounded above and tapering to a point at the bottom. The body-armor consists of a long hauberk ringed or trellised. The helmet is conical and has a sort of tongue in front which comes down over the nose.

Chain armor of interlinked rings came into use at the time of the Crusades and continued in use till the beginning of the 14th century. From the latter date to early in the 15th century mixed chain and plate armor was in use, and from about the year 1410 to the beginning of the next century the body armor was entirely of plate, and complete suits of plate armor did not altogether go out of use for another century. Below the waist the body was protected by taces, a series of narrow overlapping plates attached to a lining of leather. After the introduction of complete suits of plate armor the chief modifications consisted in the strengthening of the weakest parts, especially on the right side. By the end of the 15th century plate armor had attained its highest development, even the horses at that period being protected by plate armor everywhere except on the legs. By this time, in fact, the fabrication of armor had reached such a degree of perfection that it was scarcely possible for men-at-arms engaged in combat to find any spot where the armor of their antagonist could be pierced. Combatants equipped in this manner aimed accordingly less at wounding than at unhorsing one another, for a man-at-arms unhorsed was at the mercy of his antagonist, who, if he could not find any weak point where he could pierce the armor of his fallen foe, might beat him to death with the heavy mace with which he was armed. Many savage encounters of this nature are recorded by the chroniclers of the time. Usually, however, a man-at-arms when unhorsed became the prisoner of his conqueror, and many battles were decided, especially in the wars between the states of Italy, carried on by means of mercenaries, almost or altogether without the shedding of blood either on the side of the vanquisher or the vanquished. When body-armor had come to be manufactured with such perfection shields were almost entirely discarded. In England, indeed, no effigy has been found representing a man-at-arms bearing a shield of later date than the last quarter of the 14th century, from which it would seem that that defense had gone out of use even before the adoption of complete suits of plate armor. Perhaps the most characteristic portion of the body-armor of the 15th century was that which protected the feet. The coverings for the feet during this period were laminated *sollerets* (as they were called), acutely pointed or rounded off at the toes. In the following century these were succeeded by *sabbatons,* cut off square at the toes. In this century the armor gradually became less rigid and cumbrous, and often consisted of small plates of metal quilted within linen or other tissues. As the century advanced the manufacture of body-armor declined, and after the close of the century armor was worn as much for show as for real service. Metal cuirasses gave place, as a rule, to buff suits and jerkins, although the former armor is not entirely disused even at the present day. The principal weapons of the man-at-arms were the lance, sword, battle-axe, and mace, all of which were remarkable for their massiveness, as might be expected from the resistance they had to meet. The lance (see LANCE and TOURNAMENT) was the weapon which he used to unhorse his antagonist if he could not wound him with it. Two-handed swords were in common use in the 16th century. The sword-breaker, consisting of a deeply notched blade about 15 inches in length, and intended to catch and break the sword of an antagonist, belongs to the same period.

During all the time that the use of heavy armor prevailed, the horsemen, who alone were so armed, formed the principal strength of armies; and so much was this the case that infantry were generally regarded as of hardly any account. An exception must, however, be made in the case of England, the archers of which were almost at all times, before the invention of gunpowder, an important and sometimes the chief force in the army. It has been already mentioned that the Bayeux tapestry furnishes us with evidence of the fact that the Normans were provided with archers at the time of the conquest. The bows used by them were small, being little more than a yard in length. The deadly weapon afterward used by the English archers was from 5 to 6 feet in length, and the arrow discharged from it was itself a yard long. The bow used in Germany as well as that used in Italy (where steel was the material of which it was usually made) was about a yard and a half long. There is no evidence of the cross-bow having been used before the 11th century. Its use against Christians was forbidden by the Council of the Lateran in 1139. The long-bow continued in general use in England till the end of the reign of Elizabeth, and even as late as 1627 there was a body of English archers in the pay of Richelieu at the siege of La Rochelle. The cross-bow did not go out of use in the French army till the 17th century. Among the other hand-arms in use before the invention of gunpowder were the sling and the fustibale, which was nothing else than a sling with a handle to it. The large engines of war used in the Middle Ages were the same as those that had been employed by the Romans, with only slight modifications. A coat made of leather or quilted stuff, called in French *gamboison* or *gambeson,* was almost the only defensive armor of the foot-soldier during the greater part of the period of which we are now treating.

The use of gunpowder as a means of discharging projectiles and the gradual improvement of firearms effected in course of time a

complete change in all the methods and accessories of warfare. Details regarding the construction and recent improvements of large and small firearms and projectiles will be found under BOMB, BULLET, CANNON, GUN, MUSKET, RIFLE, SHELL, etc. Gunpowder was not used in Europe to discharge projectiles till the beginning of the 14th century. Cannon are first mentioned in England in 1338, and there seems no doubt that they were used by the English at the siege of Cambrai in 1339. All early cannon were breech-loaders. In the oldest form the breech consists of wedges of wood or metal, and this form was succeeded by cannons with movable breech-piece. The projectiles first used for cannon were of stone. Field-guns were introduced in the course of the 15th century. A rifled cannon of the 15th century is to be seen in the museum of The Hague. Mortars were introduced into the French army in 1634. Hand firearms date from the 15th century. The Swiss at the battle of Morat in 1476 are said to have been provided with 6,000 arms of this kind. In England the yeomen of the guard were armed with them in 1485. At first they required two men to serve them, and it was necessary to rest the muzzle on a stand in aiming and firing. Lighter hand-firearms called petronels seem to have been first used by cavalry. Hand-firearms were at first fired in the same way as cannon, by means of a slow match carried in the hand and applied to the powder at the touchhole. The first improvement was the invention of the matchlock about 1476. In the matchlock the slow match was held at the end of one arm of a bent lever attached to the side of the piece in such a manner that by the action of a trigger it could be brought down upon the powder in the pan at the touchhole. This kind of lock was superseded by two others, the wheel-lock and the snaphance, that seem to have been invented about the same time early in the 16th century, although the matchlock contined in use long after that date, and indeed was not altogether abandoned till the beginning of the 18th century. The wheel-lock is generally said to have been invented at Nürnberg, and was largely used in Germany. It consisted of a steel wheel which was made to revolve by a spring, and in revolving struck fire from a flint, and at the same time lifted a cap which kept the powder in the pan from being wet by rain or blown away by the wind. The chief objection to it was that it was slow in its operation, as the spring had to be wound up every time it was used. The snaphance was largely used in the Spanish dominions. It was the immediate predecessor of the flintlock, from which it differed only in making the flint strike against a fixed upright piece of iron in front of the powder-pan, while in the flintlock this upright piece was attached to another piece that covered the pan and which turned on a hinge, so that when the flint descended and struck sparks from the iron it at the same time uncovered the pan. The flintlock was invented in France about 1640, and gradually came into universal use, until it was itself superseded by the percussion-lock. This last was patented by a Scotch clergyman named Alexander Forsyth in 1807, and had been adopted everywhere by the year 1820. The first model of the needle-gun was made in 1827 by J. N. Dreyse of Erfurt. It was first made breech-loading in 1836. The only important weapon not a firearm that has been invented since the introduction of gunpowder is the bayonet, which is believed to have been invented about 1650. The socket-bayonet, fitted round the muzzle of the gun, was introduced into the French army by Vauban.

The earliest collection of arms and armor was that made by Louis XII. at Amboise in 1502. There is a fine collection at Dresden, begun in 1553. Among others may be mentioned the Ambras collection, commenced in 1570, now at Vienna, and those at Turin, Sigmaringen, Tsarsko-selo, St. Petersburg, Madrid, and in the Tower of London. The last mentioned was classified by Dr. Meyrick, and catalogued by J. Hewitt. The Antiquarian Museum of Edinburgh is rich in weapons of the stone and bronze periods, but has few specimens of arms and armor of more modern times. Of works specially devoted to the subject of arms and armor the most worthy of mention are: Grose, 'Treatise on Ancient Armor and Weapons' (1785–6; Supp. 1789; afterward annexed to the second edition of the same author's 'Military Antiquities,' 1801), and Meyrick's 'Critical Inquiry into Ancient Armor as it existed in Europe, but particularly in England, from the Norman Conquest to the reign of King Charles II.' (1824). An excellent compendium on the subject by Auguste Demmin was published in 1869 in French, English, and German. The title of the English edition is 'Weapons of War'; it gives a history of arms and armor from the earliest period to the present time. See ARMAMENT OF THE WORLD.

Arms, Stand of, the outfit of arms necessary for the equipment of a single soldier.

Armstead, Henry Hugh, a noted English sculptor: b. in 1828. He executed many allegorical groups on the Albert Memorial, London, and several fine recumbent effigies in Westminster Abbey.

Arm'strong, Sir Alexander, an English physician: b. in Ireland about 1820; d. 5 July 1899. He was educated at Trinity College, Dublin, and at the University of Edinburgh; and became widely known as an explorer. Entering the British navy at an early age, he served in many parts of the world, took part in an expedition to Xanthus in Syria; spent five consecutive years in the Arctic regions, searching for Sir John Franklin; and circumnavigated the American continent, in which voyage he became one of the discoverers of the Northwest Passage. For several years he was director-general of the medical department of the British navy. His publications include 'A Personal Narrative of the Discovery of the Northwest Passage,' and 'Observations on Naval Hygiene, Particularly in Connection with Polar Service.'

Arm'strong, David Maitland, an American genre and decorative artist: b. near Newburg, N. Y., 12 June 1837. He was graduated from Trinity College, Hartford, Conn., in 1858; practised law a few years, and then studied art in Paris and Rome. He was United States consul-general for Italy for four years, and director of the American Art Department at the Paris Exposition in 1878, receiving the Legion of Honor

decoration for his services. For many years he was at the head of a decorative glass establishment in New York city.

Armstrong, George, called the «Father of the United States Railway Mail Service»: b. Armagh, Ireland, 27 Oct. 1822; d. Chicago 5 May 1871. His parents came to the United States when he was eight years old and settled in Baltimore. He entered the postal service in Washington when a young man, and his ability won him promotion in 1854 to assistant postmaster at Chicago. He then made a study of mail transportation, wrote exhaustively on the subject, and in July 1864 was given authority by Postmaster-General Montgomery Blair to experiment on any railroad he might select. The first trial took place on the Northwestern Railroad 28 Aug. 1864, between Chicago and Clinton, Iowa, and was a complete success. He was the head of the service from the start but was assigned to headquarters in the West, with general supervision of the service in the East. In 1869 President Grant directed that a bureau be made of the railway postal service, and placed Armstrong at the head as general superintendent, a position which he held until his death two years later. A bronze statue in memory of his work was erected in the post-office building, Chicago, in May 1881. See POSTAL SERVICE IN COMMERCE.

Arm'strong, John, an American author and soldier: b. Carlisle, Pa., 25 Nov. 1758; d. Red Hook, N. Y., 1 April 1843. He served in the War of the Revolution on the staff of Gen. Gates. He was United States minister to France, 1804–10, and afterward to Spain; and secretary of war, 1813–14. He wrote the 'Newburg Addresses' in 1783, anonymously, with the intent to arouse Congress to redress army grievances. He also wrote 'Notices of the War of 1812' (1836).

Arm'strong, Samuel Chapman, an American educator: b. Wailuku, Maui, Hawaii, 30 Jan. 1839; d. Hampton, Va., 11 May 1893. He was a son of Richard Armstrong, one of the earliest American missionaries to Hawaiian Islands and founder of their educational system. The son was educated at Oahu College, Honolulu, till 1860, and graduating from Williams College in 1862, at once entered the Union army. He served till the end of the Civil War and was mustered out with the rank of brigadier-general of volunteers. In 1866 Gen. O. O. Howard, who had noted Armstrong's interest in the colored troops, induced him to take a position with the Freedman's Bureau, where he was charged with the oversight of all colored people in 10 Virginia counties. After two years of successful administration, during which he had worked out a careful plan of negro education, he enlisted the aid of the American Missionary Association and personal friends in the North, and founded the Hampton Normal and Agricultural Institute. Its object was to give the negroes practical education, to train teachers, and to render its graduates self-supporting. For 10 years the students were negroes exclusively; then (1878) the United States government, attracted by Armstrong's success, arranged to have Indian children taught there. This experiment has also proved successful. Gen. Armstrong devoted his life to the school and made it the best known and studied one of its kind in the world. At his death it had 100 teachers and employees, 200 Indian and 600 colored students.

Arm'strong, William George, Baron, an English engineer and mechanical inventor: b. Newcastle-on-Tyne, 10 Nov. 1810; d. 27 Nov. 1900. He was trained as a solicitor, and practised as such for some time, though his tastes scarcely lay in that direction. Among his early inventions were the hydro-electric machine, a powerful apparatus for producing frictional electricity, and the hydraulic crane. In 1847 the Elswick works, near Newcastle, were established for the manufacture of his cranes and other heavy iron machinery, and these works are now among the most extensive of their kind. Here the first rifled ordnance gun which bears his name was made in 1854. (See ARMSTRONG GUN.) His improvements in the manufacture of guns and shells led to his being appointed engineer of rifled ordnance under government, and he was knighted in 1858. This appointment came to an end in 1863, since which time his ordnance has taken a prominent place in the armaments of different countries. He was raised to the peerage as Baron Armstrong in 1887.

Arm'strong Gun, a description of rifled cannon, named from its inventor, the late Baron Armstrong. It is constructed of small pieces of the very best wrought-iron in the following manner: Bars of wrought-iron, having a width of 2 inches, are raised to a white heat and then twisted round a steel bar or core, and other bars are twisted successively over these till the requisite degree of thickness and strength is obtained. The various layers of bars are then firmly welded together at a white heat by the steam-hammer. Two of these welded pieces, each of them having a length of three feet, are trimmed and adjusted at the ends, which are brought close together, and united by a ring of wrought-iron, bound round them at a white heat. The length of the gun may be increased by lengthening or adding to the number of welded pieces. The steel bar which formed the core of the gun is now removed, and the sides of the bore rifled with upward of 40 small close grooves. The advantages secured by the Armstrong gun were at once manifest as of the highest importance. Its range exceeded 9,000 yards, or upward of 5 miles, being about three times the extent of that of an old-type cannon. Its precision of firing is also remarkable; and a target 9 feet square, placed at distance of 4,000 yards, has been hit 90 times in 100. At 1,000 yards' distance an Armstrong gun has hit every time an object which, aimed at by the same gunner with an old 32-pounder, has been missed 56 times out of 57. Another great advantage possessed by this description of gun is its lightness, an ordinary 32-pounder weighing 56 hundredweight, while Armstrong's 32-pounder weighs only 20 hundredweight. Lastly, the charge of powder required is only about half the quantity necessary for an ordinary cannon, and the number of times which the piece may be discharged without exhibiting any injury far exceeded anything recorded in the history of gunnery down to the time of its invention. See ORDNANCE.

Ar'my. Among nations of antiquity all men capable of bearing arms were liable to be called on to serve as soldiers, with the exception of the Egyptians, Indians of Aryan race, and Israelites. In the first two of these nations the warrior formed a separate class or caste of the community, ranking next in dignity and influence to that of the priests. In Egypt the military caste shared with the king and the priests the whole of the soil. The members of the caste were interdicted from all handicrafts. The Egyptian infantry was mainly composed of archers. Foreign auxiliaries were also employed, but kept in a strictly subordinate position, except under the last native kings of Egypt; and the different policy pursued by them was without doubt in a great measure to blame for the easy conquest of Egypt by Cambyses. In India the members of the warrior caste were called Kshatriyas, and after the complete subjugation of the non-Aryan inhabitants whom they found in the peninsula when it was invaded by them, seem generally to have lived an indolent life. Among the Israelites the only portion of the male population exempt from military service was of the tribe of Levi. In the other tribes all men above 20 might be called upon to serve in the army when occasion required. At first the army of the Israelites consisted entirely of infantry. David introduced charioteers, and Solomon added a regiment of cavalry. In later times an Egyptian auxiliary cavalry is sometimes found serving in the Jewish armies. The beginning of a standing army was made by Saul, who raised a body-guard of 3,000 men. After the captivity a new organization developed itself under the Maccabees. John Hyrcanus raised an army of foreign soldiers, chiefly Arabs.

From the monuments found in the valleys of the Euphrates and the Tigris we learn that at an early date the Assyrians, Babylonians, and Medes possessed armies of infantry, cavalry, and charioteers, and divided into light and heavy armed troops, distinguished by dress, equipment, and arms. But it was after the establishment of the Persian empire that the army system of the East attained its highest point of development. When the Persians had extended their empire over almost the whole of western Asia it was necessary to maintain a standing army to keep down conquered tribes and to guard the frontiers. The various sections of this army were each levied in the province to which it belonged, and were partly stationed in fortified towns, partly distributed over the country districts. Their pay was derived from the revenues of the province, but their commanders were wholly independent of the satraps or provincial governors. Yearly reviews were held in order to see that they were constantly kept in a state of efficiency. The troops of the standing army included a light and a heavy infantry, as well as strong bodies of cavalry, part of whom were clad in armor. The subdivisions of the army (both cavalry and infantry) were according to the decimal system. Originally all the forces were Persians, but in later times Asiatics and Greeks were also enrolled. Express messengers, stationed throughout the empire at the distance of a day's journey from one another, formed the means of communication between the different parts of the army. In addition to this provincial force the king had a body-guard of 10,000 men, called the immortals, from the fact that their numbers were always kept full. When great expeditions (such as the invasions of Greece) were undertaken a levy of the whole people was made. Fifty-six nations, according to Herodotus, were represented in the levy made by Xerxes for his celebrated Greek expedition.

In the small free states of Greece the armies consisted of a civic militia, in which it was the right and duty of every freeman to serve. In times of emergency the slaves also were armed. The Greek armies often consisted exclusively of infantry. Athens never had more than 1,000 cavalry. The foot soldiers were divided into *hoplitai*, or heavy-armed, whose equipments consisted of a long lance, a sword, and a large shield; *peltastai*, armed with a short spear, and carrying a small round shield; *psiloi*, carrying no shields, and armed only with javelins, bows and arrows, or slings; and *gymnētes*, also without shields, and chiefly composed of slaves and foreigners. The age for military service was 20 to 40 at Athens and 20 to 60 at Sparta. In Athens, however, every youth was enrolled at the age of 18, although not liable to be called on for active service till he had reached the age of 20. The command of the Athenian army was divided between 10 generals, who were elected for one year, one by each of the 10 Attic tribes, and each of whom had the chief command in turn for one day, when they were all present with the army. To obviate the manifest inconvenience of this arrangement nine of the generals were sometimes left behind, and sometimes one of the archons called the Polemarch took the field, in which case the duties of a commander-in-chief were in a great measure left to him. Until after the Peloponnesian war Athenian soldiers received no pay, but from that date a small pay was given to those in the field. At Sparta the command of the army belonged to the two kings, and usually two armies were formed, each king having the command of one of them. When only one army was formed one of the kings remained at home. Although in Sparta, as in Athens, the army consisted of the free citizens generally, yet, as in the former city it was always kept ready for war, it constituted a kind of standing army. It was divided into five *moras* or regiments, one for each tribe. After the time of the Peloponnesian war it became more and more common for all the Greek states to employ mercenary troops, and the Greeks themselves often entered into foreign service. The Macedonian standing army was created by Philip, and from the time of Alexander was composed chiefly of mercenaries. The Carthaginian armies consisted in large part, and indeed mainly, of mercenaries. The body-guard of the general, called the "sacred band," was, however, entirely made up of Carthaginians by birth, but was distinguished less by its valor than by the splendor of its equipments. In the army of Hannibal, Gauls, Iberians, and Ligurians formed the main force; Numidian cavalry hovered on the wings; Balearic slingers and elephants led by Ethiopian masters were drawn up in front. In Rome every citizen from the age of 17 to 46 was bound to serve in the army till he had made 16 (or in emergencies 20) campaigns on foot or 10 in the cavalry, and no citizen could become a candidate for any magiste-

rial office unless he had been 10 years on foot or 5 mounted. During the best times of the Roman army the troops were selected with great care, and the discipline and training of the legions were admirable, so that the Roman infantry (of which the legions were mainly composed) was the best the world had yet seen. The Roman cavalry, on the other hand, was numerically weak, and was excelled by the Numidian, and still more so by the Parthian. Pay was given to the Roman troops from the time of the siege of Veii (406 B.C.). When the Roman empire in the West fell to pieces, in consequence of the repeated inroads and settlement within its borders of German tribes, there was an end for the time to all regular army organization in western Europe. The forces by means of which the Roman empire had been gradually dismembered consisted, like the Persian hordes that 1,000 years before had conquered western Asia, of armed nations; but a new military organization, greatly inferior, however, to that of the Romans, grew up in process of time out of an institution common to all the German tribes. This was the practice followed by the chiefs of gathering round themselves bodies of retainers constantly ready to fight under them, in the expectation of being rewarded out of the spoils of conquest. As long as the Germans were confined to their original settlements outside the Roman empire these bodies of retainers bore a small proportion to the total strength of the armed population; but when extensive conquests of land were made within the Roman empire more or less of the conquered territory was always seized by the conquerors, and the personal retainers of the conquering chiefs were often so richly rewarded that the retinues of the chiefs were rapidly swelled by the adhesion of those who hoped for equal gain. At first these grants were looked upon simply as rewards for past services, but they soon came to be given and received as pledges of future service, every person receiving a grant being bound to serve his chief in war whenever called upon. In this way the feudal system, as it is called, gradually arose, and feudal armies finally superseded the national levies of the German tribes. When Charles Martel conquered the Saracens at Tours in 732 the transition from national to feudal armies was not yet accomplished, but it was almost completed under Charlemagne at the end of the same century. The chief strength of the feudal armies lay in the men-at-arms, who were all mounted, heavily armed, and protected by shields and defensive armor. After the introduction of firearms, shields and armor ceased to be an effectual protection, personal valor and bodily strength became of less moment, disciplined armies were found to be necessary, and the knights entered these armies as officers. The military forces of the small states that rose up in Italy from the 12th century resembled those of the states of ancient Greece in being at first nothing more than a civic militia. In later times hardly any troops were used, but mercenaries were employed, led by *condottieri*, and these at last were superseded by standing armies.

Among the countries of modern Europe the foundation of a standing army was first laid in France. In 1439 Charles VII. of France issued an ordinance called the ordinance of Orleans for the creation of a number of troops of horse (hence called *compagnies d'ordonnance* or ordinance companies), which were to be maintained by the cities and villages in war and peace. In 1448 the same king established a corresponding body of infantry called *Francs-archers*. Henceforward the feudal militia fell more and more into disrepute, and the vassals assembled their forces only on occasions of great emergency. The example of France was followed elsewhere, and during the wars of Francis I. and Charles V. at the beginning of the 16th century, France, Germany, and Spain were all in possession of considerable standing armies. These armies were all raised mainly by voluntary enlistment, compulsory levies being resorted to only under the pressure of exceptional circumstances. The usual practice was for the king to contract with some nobleman or gentleman for the raising of a regiment; but in the Thirty Years' war Gustavus Adolphus set the example of raising all his troops directly for his own service. In this same war, however, a whole army was raised for the emperor by a private gentleman (the celebrated Wallenstein), the emperor engaging to give him the command of it. Gustavus Adolphus was also the author of many reforms in army organization. He established smaller divisions, introduced lighter weapons, separated the pikemen from the musketeers, who had hitherto been mixed together, and made many improvements in the artillery; by all of which changes quicker and more complicated movements became practicable. The soldier was more thoroughly drilled and reduced almost to a machine, while the responsibilities of the officers were increased. The wars of Louis XIV. led to further improvements in military organization and tactics, and in a still greater degree to the increase of the size of armies. Instead of the 14,000 men maintained by Henry IV. of France, Louis XIV., after the Peace of Nijmegen (1678) had on foot an army of 140,000 men. Armies were likewise increased by all the other powers of Europe except England and Holland, where the strengthening of the standing army was looked on with great jealousy, and till the time of William III. continually opposed by the representatives of the people as dangerous to freedom. Among the military powers that came to the front in the next century the new Prussian monarchy was perhaps the most conspicuous. Frederick William I. devoted all his energies to the creation of a strong military force, and his army of 80,000 was increased by Frederick II. to 200,000. The latter introduced the system which still prevails in Prussia, and is now extended to the whole German empire, of localizing the different sections of his army. Each regiment was assigned to a certain district, which was bound to keep it at its full complement. Where voluntary enlistment did not suffice for this purpose resort was had to conscription; but this was applied only to the lowest classes of the community. The systems of drill now followed in all European armies are founded on that introduced into the Prussian army by Leopold of Dessau, who organized it under Frederick William I. Cavalry tactics were greatly improved by Frederick the Great himself, who also was the first to use horse artillery. The dividing of artillery into batteries is of about the same

date, but is due to a Frenchman named Gribeauval.

Since the time of Frederick the Great a great change has taken place in the composition of armies through the reintroduction of the principle of the universal liability of all men capable of bearing arms to military service, or, in other words, through the raising of armies by a general conscription, now practised in every European country except England. Conscription was first adopted by France in 1798, and it was by means of it that Napoleon was able to raise the large armies with which he overran and conquered a great part of the Continent. In 1808 it was adopted by Prussia, by which power it has been applied with greater rigor than by any other. In Prussia it was combined with the short-service system, a mode of training the population to arms suggested by Napoleon's attempt in the Peace of Tilsit to limit the Prussian army to a certain strength. This system consists in requiring those serving in the active army to remain under arms for a comparatively short term (in Prussia three years), during which they become thoroughly trained soldiers ready for active service on any emergency. Every year a certain number return from the army to civil life, and are replaced by others who are subjected to military training for the same term. By this means Prussia, while never maintaining a larger active army than that prescribed by the Peace of Tilsit, was able to train its whole able-bodied male population to arms, and that without allowing the fact to be discovered until it was made manifest by the war of revenge in 1813. In other countries where the principle of conscription had been adopted its operation was greatly weakened by the numerous exemptions that might be obtained, and especially by allowing those required to serve to obtain exemption by paying for a substitute. Especially was this the case in France, where, under Napoleon III., the army had again become to all intents and purposes a professional one. In army organization the principal change that has been made since the introduction of conscription has been the establishment of army corps (*corps d'armée*), that is, divisions of an army composed of all arms (infantry, cavalry, and artillery), and placed under the command of a single general. These divisions were first established by Napoleon, who placed them under the command of his marshals. The division was afterward adopted by Prussia and extended to the German empire, where the further improvement is made of localizing each army corps in a certain province or member of the empire, in which it is reunited, and in which are kept all the arms and other equipments necessary for its mobilization. In the Prussian army the cavalry are very numerous, and are used principally on the march, when they are sent in front to cover the advance of the main body of the troops, and to collect information. In all armies considerable changes in tactics have resulted from the increased range, precision, and rapidity of fire of the improved artillery and musketry now in use.

In most nations, will now be found an army of reserve, intended to augment the standing army from a peace to a war strength, and consisting of two classes — those waiting an immediate call to arms, if required, and those constituting the militia — the entire effective military power of the state. It may be of interest here to mention certain distinctions in the application of the word army. A covering army is encamped for the protection of the different passes or roads which lead to the town or other place to be protected. A siege army is ranged around or in front of a fortified place, to capture it by a regular process of besieging. A blockading army, either independent of, or auxiliary to, a siege army, is intended to prevent all ingress and egress at the streets or gates of a besieged place. An army of observation takes up an advanced position, and by celerity of movement keeps a close watch on all the manœuvres of the enemy. An army of reconnaissance has a more special duty at a particular time and place, to ascertain the strength and position of the enemy's forces. A flying column is a small army carrying all its supplies with it, so as to be able to operate quickly and in any direction, independently of its original base of operations.

ARMIES OF THE WORLD.— The following table shows the armed strength of the military nations of the world as reported in 1900:

Argentine Republic.— Regular army, 945 officers and 312,073 men; national guard, 480,000 officers and men.

Austria-Hungary.— Peace footing, 24,583 officers and 333,628 men; war footing, 45,238 officers and 1,826,940 men; levy in mass, over 4,000,000.

Belgium.— Peace footing, 3,419 officers and 48,014 men; war footing, 4,466 officers and 143,628 men; Garde Civique, 42,827 officers and men.

Bolivia.— Peace footing, 1,021 officers and 2,000 men; war footing, 82,000 officers and men.

Brazil.— Peace footing, 4,000 officers and 24,160 men; gendarmerie, 20,000.

British Empire.— Regular army, 8,109 commissioned officers, 1,087 warrant officers, 17,100 sergeants, 3,941 musicians, and 150,267 rank and file; reserves, regular, first and second classes, 83,000 officers and men, militia, 138,961, yeomanry, 11,891, volunteers, 263,963; total home and colonial forces, 669,259; regular forces on Indian establishments, 73,162; grand total, 742,421 officers and men, of whom 664,189 were classed as effectives. Owing to the war in South Africa these numbers were increased considerably during the early part of the year.

Chile.— Regular army, 623 officers and 29,282 men; national guard, 512,700.

China.—The Eight Banners, about 300,000 officers and men; Ying Ping (national army) from 540,000 to 600,000 men; active armies of the Centre, Manchuria, and Turkestan, number unknown; total land army on peace footing about 300,000; on war footing, about 1,000,000.

Colombia.— Peace footing fixed at 1,000, in 1898; war footing fixed by Congress as circumstances may require.

Costa Rica.— Peace footing, 600 officers and men, and 12,000 militia; war footing, 34,000.

Denmark.— Peace footing, 800 officers and 9,000 men; war footing, 1,350 officers and 58,600 men.

Ecuador.— Peace footing, 3,341 officers and men; war footing, 30,000.

Egypt.— Regular, about 100 English officers

and 18,000 men. The English army of occupation numbers 5,553 officers and men.

France.— Peace footing, 26,849 officers and 520,666 men, with 140,912 horses; in Algeria, 2,195 officers and 55,122 men; in Tunis, 560 officers and 13,455 men. Active army and its reserve, 2,350,000; territorial army, 900,000; territorial reserve, 1,100,000; total, 4,350,000 men of whom about 2,500,000 were effectives.

German Empire.— Peace footing, 23,176 officers and 562,277 men, with 98,038 horses; war footing, strength not officially published, but estimated at over 3,000,000 trained officers and men. There are 494 field batteries, of which 47 are mounted.

Greece.— Peace footing, 1,880 officers and 23,453 men; war footing, about 82,000 men; territorial army, about 96,000 men.

Guatemala.— Peace footing, about 7,000 officers and men; war footing, 56,900 men.

Haiti.— Peace footing, 6,828 officers and men, and special guard of 10 officers and 650 men.

Honduras.— Peace footing, 500 officers and men; with 20,000 militia.

Italy.— Permanent army, under arms, 14,324 officers and 237,660 men; on unlimited leave, 556,984 officers and men; mobile militia, 475,972 officers and men; territorial militia, 10,793 officers and 2,003,474 men; total officers and men, 3,299,439.

Japan.— Imperial Guard, 370 officers and 10,843 men; 6 divisions, 2,745 officers and 73,606 men; reserves, 696 officers and 82,384 men; Yezo militia, 95 officers and 4,482 men; the gendarmerie, 51 officers and 1,011 men; territorial army, 357 officers and 104,597 men; total strength, 4,760 officers and 279,981 men, with about 29,000 horses.

Kongo Free State.— Peace footing, 234 European officers and 173 sergeants, and 15,580 native troops.

Korea.—An army of 5,000 officers and men.

Madagascar.—An army of 191 officers and 5,508 men.

Mexico.— Peace footing, 2,068 officers and 30,095 men; war footing, including reserves, 151,500 officers and men.

Montenegro.— No standing army; all males physically able are liable to military service; there are about 100,000 rifles in the country.

Morocco.— Peace footing, about 12,000 officers and men, and 18,000 militia; war footing, in addition, about 40,000.

Netherlands.— Peace footing, 1,466 officers and 40,195 sub-officers and soldiers; war footing, indefinite.

Nicaragua.— Peace footing, 2,000 officers and men; war footing, in addition, 10,000 reserve and national guard, 5,000.

Norway.—Troops of the line and reserves, 900 officers and 30,000 men; not over 18,000 troops can be put under arms, even in war, without consent of the Storthing.

Orange Free State.— Standing army, 150 officers and men, and 550 artillerymen, as a reserve; available war strength, 17,381.

Paraguay.— Standing army, 82 officers and 1,345 men; every male 20 to 35 years old is liable to war service.

Persia.— Standing army, 24,500; nominal, 105,500; liable to service, 53,520.

Peru.— Peace footing, 3,157 officers and men with a police force of from 2,000 to 3,000.

Portugal.— Peace footing, 35,337 officers and men; war footing, 160,000; colonial forces, 9,478 officers and men, the greater number being native troops.

Rumania.— Peace footing, 3,478 officers, 448 employees, and 56,489 men, 12,675 horses, and 390 guns; territorial army 75,000 men, and 8,050 horses; war footing, indefinite.

Russia.— Peace footing, 36,000 officers and 860,000 men; war footing, 63,000 officers and 3,440,000 men.

Salvador.— Standing army, 4,000 officers and men; militia, 18,000.

Santo Domingo.— Small army and reserve at the capital of each province, every physically able male liable to service.

Servia.— Standing army, 160,751 officers and men; war footing, 353,366 officers and men.

Siam.— Standing army, 12,000; no armed militia; all males liable for war service.

South African Republic.— No standing army; males liable for war service, 26,299.

Spain.— Peace footing, 128,559 officers and men; war footing, 183,972 officers and men.

Sweden.— Standing army, 1,946 officers and 37,175 men.

Switzerland.— No standing army; war effective, Elite, 147,191 officers and men; Landerwehr, 83,283; Landstrum, 271,780.

Turkey.— Standing army, 700,62c officers and men; war footing, 900,000.

United States. See ARMY OF UNITED STATES.

Uruguay.— Permanent army, 233 officers and 3,222 men; armed police force, 3,200; national guard, 20,000.

Venezuela.— Standing army, 3,600 officers and men; national militia (males 18 to 45 years old), 60,000 men.

Army and Navy, Mutual Relations of. The campaign of the United States army and navy in the Caribbean region, while instructive from many points of view, has especial value at the present moment to the people of the United States, as illustrative of certain necessary outlines of our future naval and military policy. Estimating at the lowest the permanent results of the late war, the nation finds itself charged with valuable transmarine possessions, which have not merely to receive the local defence which is — or should be — common to the country in general, but must also, for the welfare of the Commonwealth, be knit to the home body by the only military bonds that can cross the stretch of the seas. Local protection is indeed imperative; but from the military point of view, national defence, in any real sense, cannot be said to exist when the localized defences are not knit together and co-ordinated into a system, which insures freedom of communication and thereby mutual support. Gibraltar and its rock are the proverbial synonym of impregnability; yet Gibraltar in its time not only has fallen by local neglect, but has more than once narrowly escaped a like fate through inferiority of naval force — through severance of communications with the body of which it is a member.

The fortified places upon which a system of defence rests are stationary. They contribute to the general safety, directly, only so far as their guns can range, or as conducive to delay in case of attack; but when to them is added a mobile force, which either issues from them to assume the offensive, or which, in its move-

ments, in the open, knows that in them security can be found in case of reverse, the various members are brought into a living union, wherein each contributes its proportion to the strength of the whole. On land such mobile force is represented by the active army in the field; at sea by the fleet. Both need the support of stationary fortifications; and both, as has just been said, are essential in turn to the fortresses themselves. Jomini has truly said, "When a state depends wholly upon fortified places (that is, upon mere defence) for its safety, it has touched the verge of ruin." It may be deemed fortunate, that at the moment of starting upon a new career, the United States received an object lesson in the mutual relations of army and navy, of stationary defences to mobile force; a dramatic presentation of the part played by each, not only on the field of battle, but in the general maintenance of national security and power. Upon this living picture the eyes of the whole nation were fixed, with the vivid interest which always follows the progress of arms. The campaign against Cuba — and especially against Santiago — by sea and by land, has for us the particular value that it lies wholly within our own experience, and speaks to us therefore with the force which belongs to experience alone among the teachers of mankind.

It is wise, says an old proverb, to learn from one's enemy. Let us, for our instruction, turn our eyes for a moment upon our recent enemy, upon him who 400 years ago, in the heyday of Europe's adolescence, went forth, a youth among other youths, to possess the land, and who now returns a discomfited prodigal, abandoning the last of the fair heritage upon which he, favored above his fellows, then entered. It is not indeed admissible in a short article, dealing avowedly with a particular brief episode of history, to attempt to trace the general causes of Spain's downfall. Suffice it to note, in pursuance of our previous allegory, that from the beginning Spain's ideas, both individual and national, carried within them the seeds of inevitable and early blight. She shared with her contemporaries the restless ebullience of early manhood, as the nations were breaking out of the nursery of tradition and authority; but she went forth imbued, not with principles of action, but with mere habits of thought, externally imposed, and accepted without the self-questioning that comes from the collision of mind with mind. So, while the world was growing, Spain grew not. A century after America was discovered, she was in thought and method just where Ferdinand and Isabella were; as it is recommended to us now to remain just where Washington or Jefferson, under different conditions, stood 100 years ago. The colonial system of Spain, which gasped its last this year, continued essentially the same from the beginning to the end; even as we are told by foreigners familiar with the peninsula that people there live for the most part in the ideas of centuries ago. Shock after shock failed to loosen the hold of tradition, and it may be doubted whether even the final crash will penetrate through men's ears to the brain.

One thing Spain has never been since the time that the unity of the peninsula was achieved — a maritime nation. Seamen, doubtless, she has had; it would be rash indeed to deny that name to the men who accompanied Columbus, although the great adventurer was himself Italian; but for all that, as a nation, the heart of Spain has never turned to the sea. Yet Great Britain herself was scarcely more favorably situated for the development of maritime instincts and maritime power. Like France, Spain borders the Atlantic and the Mediterranean; but above France she possessed the advantage that her only land frontier (leaving little Portugal out of account) was a lofty and difficult mountain range. Like the United States of to-day, which borders the Atlantic and the Pacific, Spain was practically an insular power; for, unlike the United States in the days of Washington, she had no dangerous continental frontiers. In this security from attack by land, in the power of her sovereigns, unrivaled in the 16th century, in her remoteness from the turmoil of central Europe, and in the one single danger to which she was exposed — the ravaging of the coasts by the Mohammedan pirates — was found a combination of circumstances, which, so far as external pressure molds character, should have made Spain a respectable, if not a great, naval state. From the resources and exposure of her extensive and lucrative colonies there arose an additional incentive to commercial and naval development; but none followed. The root of the matter was not in her. What she was, that she remained. Often rebuked by disaster, she hardened herself against change; until, in the end, she has suddenly been destroyed, and that without remedy.

Yet no people more than the Spaniards understood and practised the art of fortification as it existed in the days of their power. It was not lack of local defences that enfeebled the colonial empire of Spain, and so often caused particular localities to fall before an invader. It was the lack of control over the communications — over the sea, by which alone communication could be had — which permitted the enemy to assemble his forces with impunity, and prevented the Spaniards from reinforcing where needed; in a word, it was defect in the sea power, which insures mutual support and the possibility of offensive action. Defence, whether greater or less, only imposes delay; and delay must be improved, or it is useless. Like a burglar at a safe, so is the besieger; except that interruption may come, the time more or less does not matter. The essential thing for the party who, as regards the war, is on the defensive — who has the most to lose — is to retain in his hands the power to move at will and rapidly from point to point; not merely to defend locally, but to attack the assailant either in transit, or at his point of destination; or, it may be, even by offensive operations on the enemy's own coasts. Such power — sea power — Spain has never had. The material elements she did indeed from time to time create. "I never saw finer ships," said Nelson a century ago. "The Dons make fine ships; they cannot, however, make men." This manifests again the impotence of mere government, or external compulsion, to impress upon man or people qualities which find within no root of life, native or implanted. In the inward realm of ideas, diffused among the people, is the true strength of nations to be found. May we heed the warning.

The history of four centuries only repeats itself in miniature when the final scene in the

long drama of Spain's colonial history is critically regarded. The last Cuban revolt had continued already three years when the United States intervened. During that period, Spain had sent over 200,000 soldiers to her colonies, and had incurred an extraordinary expenditure of some $400,000,000 for the campaigns; an immense effort, whether regarded in itself alone, or relatively to the resources of the mother-country. Yet, although the mutterings that ran throughout the United States were audible in Europe, and it could have been plainly recognized that behind a mere political bluster there was unquestionable popular impulse — a most dangerous condition — no important addition was made to the fleet. Even the vessels on hand, antiquated though some were, were not brought up to the full efficiency they might have received. Cervera sailed with but four ships. Not till six weeks later was Cámera able to get away, and then there went with him only two armored vessels. The inference is reasonable that such others as there were — and there were others — could not be got ready; that even the nominal force was not available. Yet one thing demonstrably certain is, that had the Spaniards maintained a navy superior to our own, the expense of which would have been far less than the cost of their troops in Cuba, it would have excluded us from the island, which otherwise its fortifications and armies could not do. It may be assumed, indeed, that had the Spanish navy been decisively superior to our own we would have refrained from war, unless determined to it by the loss of the Maine; for nothing so certainly maintains the peace as the evident readiness of the enemy. This the great armies of Europe now show. As it was, when Cervera was shut up in Santiago, we dared to send 15,000 men a thousand miles by sea, to land at the very mouth of the harbor; and after this squadron was destroyed we were quite at our ease as regards the rest of the task. Utterly undeveloped as our military preparations were, we could take our time. The Spanish force in Cuba must waste; ours could not but increase. The end was thenceforth predetermined, and Spain wisely asked for peace.

Yet while this lesson is clear, and in the opinion of the writer is the one of primary importance to ourselves — as to any nation undertaking to have colonies — it would be a most incomplete and misleading view did we not further recognize the complementary element of land forces and fortifications in deciding the issue of the war. Had there remained to Spain a fleet — a "fleet in being," to use a phrase now widely accepted as technical — at all equal to our own, and able shortly to get to sea, our advantage at Santiago would have been but momentary and indecisive. The presence of the Spanish army, 100,000 strong, of as good fighting quality as the Santiago garrison is said to have shown, while it would not have controlled the whole island, would have effectually excluded us from the more important part, until the Spanish navy, temporarily eliminated by Cervera's defeat, could have again been brought into play. The co-ordinate value of mere defence would have received conspicuous illustration. The Spanish army in Cuba, and its fortifications of every kind, seacoast or otherwise, were, as regards the general war, strictly limited to the defence of the island. The communications between it and the United States — the roads — were in our hands, to transport troops as we pleased; but only temporarily so, on the present hypothesis, namely, that Spain had still a fleet which, upon arrival in the Caribbean, would have a fighting equality or superiority to ours. The question therefore at such a stage would be one of delay. Can the Spanish army keep the field until its fleet appears and exclude us from the control of the vital centre of the island? Failing this, can it even, by retiring to its fortresses, preserve its integrity, and prevent our obtaining that essential foothold for maritime enterprise, a fortified seaport close to the scene of operation — a bridgehead for entrance when ready? If so, it secures the necessary delay until the all-important decisive factor in maritime wars, the navy, can make itself again felt.

It is clear, therefore, that while an incontestable and inalienable primacy belongs to the navy in all cases of transmarine warfare, the maintenance of an adequate territorial army, resting upon proper fortified bases, is likewise indispensable, if secondary. And indeed, this hypothetical case, of a fleet remaining to Spain after Cervera's mishap, was the actual condition before that event; to the extent at least of our certain knowledge of what the Spanish navy might, or might not, be able to do. Had the enemy had no army in Cuba, and had he pursued his proper course by recalling Cervera from the Cape Verde Islands to Spain, as a preliminary to sending the concentrated fleet across the ocean, we might have sent troops to seize and strengthen themselves in Cuba's strategic ports; but, in the face of the then Spanish army, it was not possible to do so to any good effect. Consequently, we did not attempt it, until Cervera was cornered.

Probably our people at large are conscious that colonial possession involves a colonial army. This the experience of Great Britain tells us may be largely, though not wholly, aboriginal; and that the less developed the civilization of the natives, the greater the proportion of the latter may be to the whole force. But it is doubtful whether the general acquiescence in the necessity of such an army is accompanied by an exact understanding of the part it plays in maintaining possession; what its strength is, and what its weakness, considered, not in itself alone, but in relation to the whole problem of national and colonial defence. The function and effect of the Spanish army in Cuba illustrate this, and therefore are important to be understood, for the appreciation, not of recent history only, but of the necessary future policy of the United States as well. The navy binds all together; without it each falls in time, isolated and unsupported. In 1762, as in 1898, in one twelve-month Spain lost both Manila and Havana, and for the same reason — defective sea power. But in order that the navy, the mobile force, may assure the whole, it is necessary that each part be able to resist attack during a measurable period, exactly as a fortress on any scene of warfare. Each colony, until it becomes self-supporting and fit for independence, is an exposed garrison. They are plausibly right, therefore, who argue that as a general rule a country does not consult its immediate interests by acquiring colonies. Their error is in failing to

recognize that immediate self-interest is not always the sole test, although it furnishes us a very adequate reason for taking Hawaii. It may be a duty to accept a responsibility which is not to one's convenience. For what other reason than duty is civic activity immediately incumbent on the well-to-do?

It is interesting to find the same conditions revealing themselves in the minutiæ of specific instances as truly as in broad generalizations. In the broad history of policy we shall find illustrated the mutual dependence of the active army and navy, of seacoast fortification and the fleet. It is a curiously ironical comment upon human foresight that the issue of the war turned upon the tenure of that one of the great Cuban ports, which at the first certainly seemed least likely to be involved, as a scene of actual conflict. From Spanish sources we learn that Cervera entered the port because it was the only one available. If such was actually the reason for this seemingly fortuitous step, he acted under a misapprehension of our dispositions. Until he had so entered, however, his squadron was the controlling factor in the general situation. The navy of the defence, though locally much inferior to its opponent, was yet too strong to justify our exposing troops upon the maritime high roads; and it rested also on several fortified ports, from any of which it might issue to attack our interests, and in which it might find refuge, when pressed for supplies or by our ships. The Spanish tenure of Santiago made the squadron therein secure; and although a singular lack of enterprise, as yet unexplained, paralyzed it as an active factor, the mere possibilities of offensive movement open to it imposed upon us its neutralization and, if feasible, its destruction. The former was insured to the utmost degree practicable when our fleet had been concentrated before the port; but from direct attack it was preserved by the territorial army, supporting the permanent fortifications and the lines of torpedoes. These cannot be overcome by ships alone, unless the assailant is able to throw away not only lives of men, who may be replaced, but ships which cannot. Those who can recall conditions at the time, not only as regards our immediate enemy, but the rumored dispositions of other states reported to be unfriendly toward us, will understand that the preservation of our navy in undiminished force was a political consideration of paramount importance. We could not afford then to lose ships, unless at the same time we diminished by at least an equal amount the naval force which might yet be arrayed against us.

Our army, therefore, was called upon to make untenable the refuge which sheltered the hostile fleet. That we were able to move our troops to the scene of action with perfect assuredness was due to the fact that our navy had established its predominance in the local waters; and conversely, Spain suffered invasion of her colony because she had lost control of the sea. Our troops, when landed, depended for their security and for their supplies upon the continuance of this maritime condition; the sea, in short, was its line of communications, which the navy protected. On the other hand, unless Cervera were forced to quit the port by famine, produced by the blockade — a not impossible contingency — the navy could not get at his ships to destroy them without the aid of the army; and destruction was necessary, for, as the French proverb says, "It is only the dead who do not return" inconveniently. The army's aid might be extended in one of two ways. Either it might — if it could — get possession of the town by its own unaided efforts, or by establishing a dominant position overlooking it; or it might direct its attempt, aided by the navy, upon the works commanding the harbor's mouth. These reduced, the navy would be able to remove the torpedoes, enter the port, and engage the hostile squadron.

These details of comment, however, do not at all affect the general propositions upon which the writer has sought to fasten the attention of his readers; the mutual dependence of army and navy, in the attack or defence of maritime regions, and the primacy therein of the navy, which represents both the communications and the offensive element of the war upon the sea. By the neglect of these considerations Spain lost her colonial empire. By the observance of them Great Britain has preserved hers, and the English-speaking race dominates the sea. In this predominance, further, are involved the issues of that mysterious future, the movings of which we are now beginning to discern, as in a glass darkly; and which the race holds within its grasp, if only through wise guidance of popular thought by those who have time to think, it can find its way, not by formal alliance but by political comprehension, to common action and to mutual support.

A. T. Mahan,
Author of 'Influence of Sea-Power,' Etc.

Ar'my Corps, a term denoting one of the largest divisions of an army in the field, comprising all arms, and commanded by a general officer; but subdivided into divisions, which may or may not comprise all arms.

Ar'my Hospital Train, a railway contrivance for military purposes, introduced by the surgeon-general of the United States army during the war with Spain, in 1898, for the purpose of conveying sick and wounded soldiers, on their arrival from Cuba, at Florida ports, to various military hospitals in the United States. This train had a full staff of physicians, surgeons, and trained nurses, and was completely equipped with everything necessary for medical and surgical treatment of soldiers. It is believed to have been the first train service completely organized for such purpose.

Ar'my Register, an annual publication of the United States government giving personal, regimental, and other details of the regular army, and corresponding to the British 'Army List.'

Ar'my Reserve, in most European armies, a force consisting of a first and second class army reserve and a militia reserve. The first class army reserve consists: (1) Of men who have completed their period of seven years in the active army, and of men who, after having served not less than three years in the active army, have been transferred to the reserve to complete the term of their engagement; (2) of soldiers who have purchased their discharge and enrolled themselves in the reserve for five years.

In time of war or when the country is threatened, the men of this class become liable for the same services as the active army. The second class army reserve is made up of enrolled pensioners, and is liable only for service at home. The militia reserve is composed of men belonging to the militia who voluntarily enroll themselves in this reserve for a period of six years, thus rendering themselves liable to be drafted into the regular army in case of war. In the United States there is no Federal army reserve, but each State maintains a militia force under the command of the governor, principally to aid the legal authorities in maintaining peace within its limits. In emergencies threatening the whole country, and where the regular army is insufficient, the President calls for volunteers, apportions the number needed among the several States, and asks the governors to supply the determined quotas. The bulk of the volunteer army is thus drawn from the miltia.

Ar'my Schools. See Army War College; Military Schools.

Army of the United States, The. The Constitution gives to Congress the power to provide for the common defense and general welfare of the United States, "to declare war," "to raise and support armies," and "to make rules for the government and regulation of the land and naval forces." The responsibility, therefore, for the common defense rests with Congress, for all the power essential to meet it is vested in the legislature of the nation, which has supreme control.

During the War of the Revolution General Washington was unanimously elected 15 June 1775, "to command all the continental forces raised or to be raised, for the defense of American liberty," but on assuming command, he found an heterogeneous and undisciplined force, and immediately took measures to bring order out of confusion; and the General having recommended to the Congress and pointed out the necessity for a war office, that body, on 13 June 1776, created a Board of War, composed of its own members, which body was the germ of the War Department of our Government. During 1781 the Continental Congress, having under consideration a plan for the arrangement of the civil executive departments, established among others the office of Secretary of War, to which Major-General Lincoln was elected, and at this juncture several acts were passed defining the duties of the office, organizing various of the Staff Corps, and providing for a military establishment.

From that period, although Congress has made appropriations for the support of the army, and passed laws for its better efficiency, the evolution of organization and equipment and of the general (administrative and supply) staff has only been accomplished through tentative measures, and to meet emergencies. It is of little interest, therefore, to review its history in this respect, for the past few years have brought about a complete revolution in the organization, equipments, tactics, and armaments of an army.

From the early history of our country the sentiment of the people as expressed through the Congress, has always been opposed to a standing army in time of peace, but the Constitution itself declares that "A well-regulated militia being necessary to the security of a free state, the right of the people to keep and bear arms shall not be infringed." It has been the continuous policy of the government to maintain only a small army, and to rely in any great war upon the volunteers, and after each, to disband the citizen soldiery and reduce the regular establishment to a peace basis.

With the exception of periods of actual warfare, the functions of the regular army are to man the seacoast fortifications, which protect our harbors and great cities from hostile attack, and to garrison the outposts on the western frontier, and at such strategic points as Congress determines to be suitable; to be always ready to fight for the country in any sudden emergency which may come upon it before there is time to raise a volunteer force, and during the time such a force is being raised; to constantly study, and experiment upon, and exercise in, all the improvements in military science, both in arms, ammunition, equipment, supplies, sanitation, transportation, drill and tactics; to furnish a nucleus of officers and men thoroughly familiar with the business for strengthening and ready instruction of the volunteer army.

Strength and Organization.— The following table shows the *authorized* strength of the regular army under the various acts of Congress from 1789 to 1901:

Acts.	Officers.	Enl. Men.
Sept. 29, 1789	46	840
April 30, 1790	57	1,216
March 3, 1791	104	2,128
March 5, 1792	258	5,156
May 30, 1796	233	3,126
April 27, 1798	289	3,870
May 27, 1798	303	10,000
July 16, 1798	783	13,638
March 3, 1799	2,447	49,244
May 14, 1800	318	4,118
March 16, 1802	241	3,046
April 12, 1808	774	9,147
June 26, 1812	1,657	34,095
March 3, 1813	3,260	54,091
March 30, 1814	3,495	59,170
March 3, 1815	674	11,709
March 2, 1821	589	5,586
April 5, June 15, 28, 1832	540	6,540
March 2, 1833	599	6,595
May 23 and July 4, 1836	647	7,310
July 5 and 7, 1838	735	11,804
May and June, 1846	775	17,020
Feb. 11 and March 3, 1847	1,353	29,512
Aug. 14, 1848	882	9,435
June 17, 1850*a*	889	11,000
March 3, 1855*b*	1,040	16,882
July 29 and Aug. 3, 1861	2,009	37,264
July 28, 1866*c*	3,036	51,605
March 3, 1869	2,277	35,036
July 15, 1870	2,264	30,000
June 16, 1874	2,151	25,000
March 8, 1898	2,137	26,610
April 26 and July 7, 1898	2,432	63,106
March 2, 1899	2,585	65,000
Feb. 2, 1901*d*	3,860	60,450

a By the Act of 17 June 1850 the President is authorized to increase the number of privates in each of the companies of the army, serving, or which may hereafter serve, at the military posts of the western frontier, and at remote and distant stations, to any number not exceeding 74, which if all had been serving at distant stations would have made the total maximum enlisted strength 13,885, the minimum being 9,385 enlisted men.

b The minimum authorized enlisted strength under the Act of 3 March 1855, was 11,658, and the maximum 17,278.

c The Act of 28 July 1866 fixed the minimum enlisted strength at 51,605, and the maximum at 77,250.

d The Act of 2 February 1901 fixes the minimum strength at 59,131 enlisted men and the maximum at 100,000, the number of officers remaining the same.

The regular army on 1 Jan. 1898, just prior to the declaration of war with Spain, consisted of 2,157 officers and 25,350 men, all told. War being imminent, the Congress during March and April, 1898, passed certain acts for the better organization of the line of the army, which authorized a maximum enlisted strength of 65,000 men; increased the artillery by two regiments; added to each infantry regiment a third battalion of four companies each; provided for additional non-commissioned officers for the regiments, squadrons, and battalions, and for the troops and companies; and the enlisted strength of each unit was considerably augmented.

By an act approved 22 April 1898, the Congress made provision for accepting into the service the militia (National Guard organizations) and volunteers from the various States, and made the following declaration with respect to the National forces:

> All able-bodied male citizens of the United States, and persons of foreign birth who shall have declared their intention to become citizens of the United States . . . between the ages of 18 and 45, are hereby declared to constitute the National forces, and with such exceptions and under such conditions as may be prescribed by law, shall be liable to perform military duty in the service of the United States.
>
> That the organized and active land forces of the United States shall consist of the army of the United States and of the militia of the several States when called into the service of the United States: Provided, that in time of war the army shall consist of two branches which shall be designated, respectively, as the regular army and the volunteer army of the United States.
>
> That the regular army is the permanent military establishment, which is maintained both in peace and war according to law. That the volunteer army shall be maintained only during the existence of war, or while war is imminent, and shall be raised and organized (as prescribed by the statute) only after Congress has, or shall have authorized the President to raise such a force or to call into the actual service of the United States the militia of the several States.

The law authorized enlistments to be made for the term of two years, unless sooner terminated, and that all officers and men composing the volunteer army should be discharged when the purposes for which they were called into service were accomplished, or on the conclusion of hostilities.

The law further prescribed that the President should issue his proclamation, when it became necessary to raise the volunteer army, stating the number of men desired (within the limits prescribed); enjoined the Secretary of War with the duty of examining, organizing (as prescribed for in the regular army), and receiving into the service the men called for, and as far as practicable these troops were to be accepted only in proportion to the population of the several States and Territories. The law also required that the organizations of the volunteer army should be maintained as near their maximum strength as was deemed necessary by the President, and prohibited the acceptance of new organizations unless those already in service from the States were kept fully recruited.

The law also authorized (in addition to those already provided for by law) the appointment of general, and general staff officers of volunteers, sufficient for the proper command of the combined forces, and permitted of regular officers holding volunteer commissions without prejudice to their regular army status.

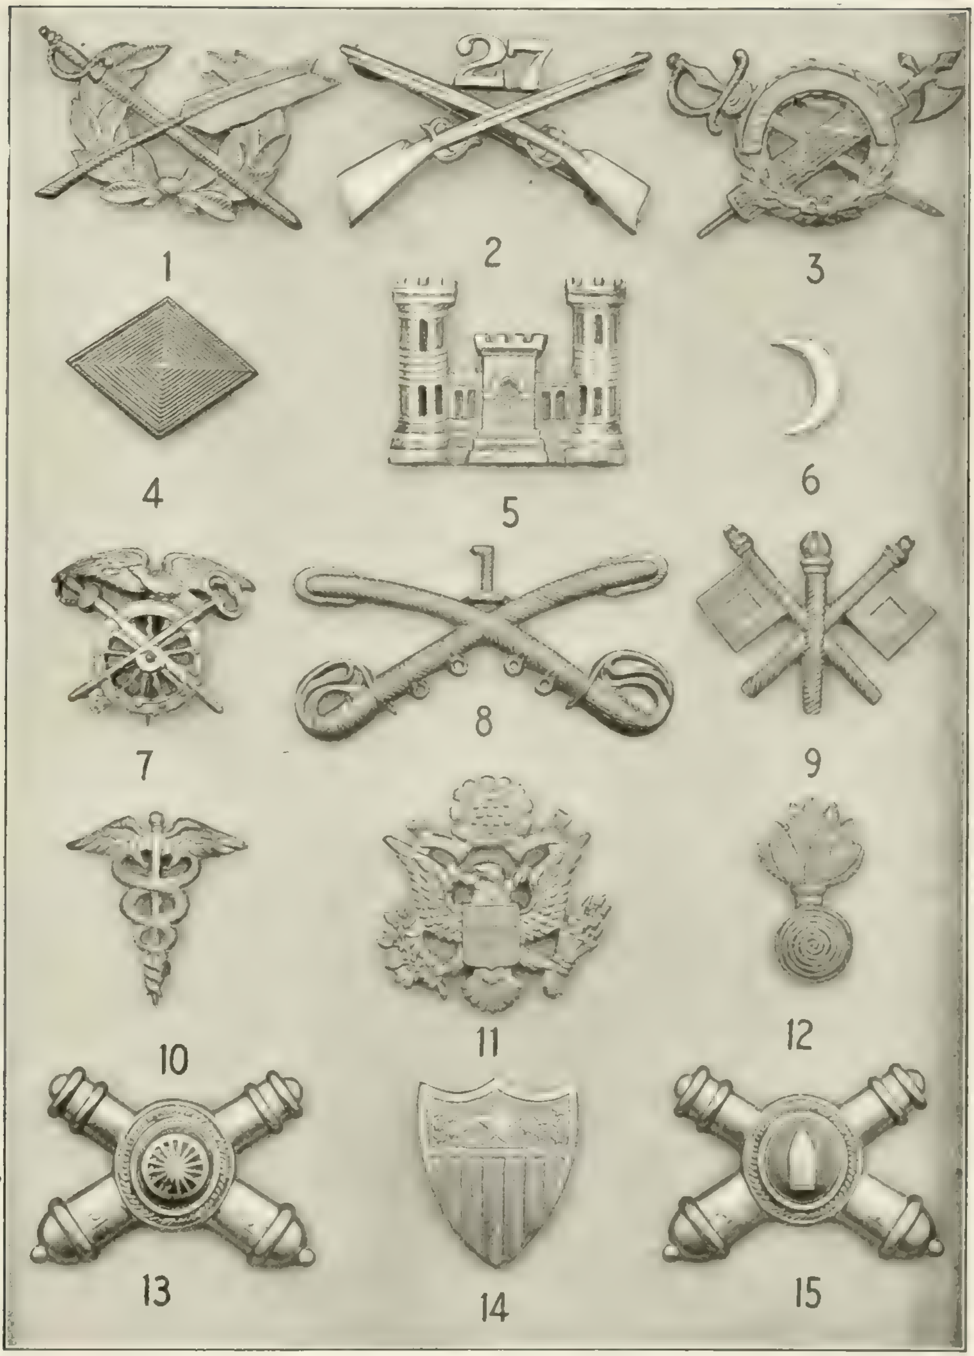
Of this army, three regiments of engineer troops, three of cavalry, and ten of infantry were United States volunteers recruited from the nation at large — all of the officers being commissioned by the President. As fast as the State troops were presented properly organized, they were mustered into the service of the United States. The total number furnished for the war with Spain was 10,017 officers (387 officers of the regular army received volunteer commissions) and 213,218 enlisted men.

The close of the war brought into operation the provisions of the acts of 22 April and 26 April 1898, which required that at the end of the war the entire volunteer forces should be discharged and the regular army reduced to a peace basis, thus making necessary the discharge of about 35,000 regular troops, 110,000 volunteers, and substantially all of the 5,000 volunteer line and staff officers.

The act of 2 March 1899, was passed in view of the insurrection in the Philippine Islands, and gave authority to again increase the regular army to a strength not exceeding 65,000 men, and to raise a force of not more than 35,000 volunteers to be recruited from the country at large — the field officers being appointed from among the officers of the regular army, 233 officers holding such commissions. All the volunteers authorized by this act were recruited and forwarded to the Philippine Islands by January 1900, and there actively employed in military operations. During that year about 42,000 men of the regular army and 31,000 of the volunteers were in service in the Philippine archipelago. This act contained the provision that all general staff and line officers appointed, and the volunteer troops raised, under its provisions, should be discharged not later than 1 July 1901 and the regular army reduced to the number as provided by law prior to 1 April 1898, exclusive of the addition made to the artillery; but the Congress, recognizing the necessity for a larger and more perfectly organized army, passed a law, which was approved 2 Feb. 1901, providing for an increase of line organizations from 25 regiments of infantry to 30, and 10 regiments of cavalry to 15, and from 7 regiments of artillery, including 14 field and 2 siege batteries, to the equivalent of 13 regiments (organized into 30 batteries of field artillery and 130 companies of coast artillery), and 5 companies of engineers to 12 companies, representing 3 battalions. The minimum and maximum numbers of enlisted men for the different arms were established by the same statute, so that the total number of enlisted men might be varied by the President according to exigencies from a minimum of 59,131 to a maximum of 100,000 (including a corps of Philippine Scouts, which is limited to 12,000), the commissioned personnel remaining the same.

The regular army is recruited (through the agency of recruiting officers maintained in the principal cities and towns) in times of peace and war by voluntary enlistments (term of service three years) from among citizens of the United States, between the ages of 18 and 35, of good character and temperate habits, able-bodied, free from disease, and with educational capacity to speak, read, and write the English language. The native born constitute about 90 per cent of the enlistments in the army.

INSIGNIA UNITED STATES ARMY.



Arranged by Harold L. Crane, N. Y. City.

1. Judge-Advocate General's Department.
2. Infantry.
3. Inspector General's Staff.
4. Pay Department.
5. Engineer Corps.
6. Subsistence Department.
7. Quartermaster's Department.
8. Cavalry.
9. Signal Corps.
10. Medical Department.
11. Coat of Arms.
12. Ordnance Department.
13. Field Artillery.
14. Adjutant General's Department.
15. Coast Artillery.

In addition to the pay ($13.00 per month for the private being the minimum), all soldiers receive from the government, rations, clothing, shelter, medicine and medical attendance, and certain increases in the fixed pay for continuous service. Soldiers can deposit their savings with the paymasters, and are allowed four per centum per annum thereon on final discharge. For those who have served honestly and faithfully 20 years, or who have been discharged for wounds received or disease incurred in service, a comfortable home is maintained in the city of Washington, toward the maintenance of which each soldier contributes 12½ cents per month from his pay, and all court-martial fines and forfeitures and pay due deserters go to the home.

In addition to the combatant force proper, the law authorizes the enlistment of musicians; for the cavalry troops, cooks, blacksmiths and farriers, saddlers and wagoners; for the artillery corps, electricians, cooks, mechanics and artificers; and cooks and artificers for the infantry. Special technical skill is required for enlistment in the engineer, signal and hospital corps.

Officers: Appointment to, Advancement in, and Retirement from the Military Service.— The power to make appointments is vested in the President and the Senate of the United States, acting concurrently, within the limits of the enactments of Congress, which do not encroach upon the prerogatives of the executive, who, under the Constitution is the Commander-in-Chief of the army and navy of the United States.

The army is officered, (1) from the graduates of the Military Academy, to which young men may be admitted between the ages of 17 and 22. Candidates must be free from any infectious or immoral disorder, and any deficiency which may render them unfit for the military service, and must be possessed of a good elementary education; the examination for entrance being made to conform to the courses of study ordinarily covered in the high schools and academies of the country by boys of average age of appointees, and they may be admitted upon certificates from educational institutions. Two cadets-at-large are allowed each State (designated by the respective Senators), and one for each congressional district, Territory, and the District of Columbia. In addition to this number the President is allowed a number of appointments, which are usually made from among the sons of officers of the army and navy.

The commanding officer of the academy, who has the title of Superintendent, is detailed from the army and has the temporary rank of colonel. For the purpose of discipline and tactical instruction, the cadets are organized as a battalion of four companies, with officers and non-commissioned officers selected from among their own numbers. The corps is commanded by an officer having the temporary rank of lieutenant-colonel. He is also an instructor in drill regulations of the three arms of the service. An officer of engineers and of ordnance are detailed as instructors of practical military engineering and of ordnance and gunnery, respectively. The heads of the other departments of instruction have the title of professors. They are selected generally from officers of the army, and their positions are permanent. The officers before mentioned and the professors constitute the academic board. The military staff and assistant instructors are officers of the army. The course of instruction covers four years, and is very thorough. Theoretical instruction comprises mathematics, French, Spanish, English, drawing, physics, astronomy, chemistry, ordnance and gunnery, art of war, civil and military engineering, international, constitutional, and military law, history, and drill regulations of all arms. The practical instruction comprises service drills in infantry, cavalry, and artillery, surveying, reconnaissances, field engineering, and gymnastics. The discipline at the academy is very strict — more so than in the army. In addition to a training and education fitting the cadets for the military service, the aim is to inculcate habits of prompt and cheerful obedience to lawful authority, of neatness, order, and regularity, and of thoughtfulness and attention to the discharge of duty. A scrupulous regard for truthfulness is also required. Upon graduation commissions for the rank of second lieutenant are usually conferred by the President, and the graduates are given a choice as to the arm of service and regiments, as far as practicable, those graduating at the head of the class having preference. The military academy, on 11 June 1902, celebrated with appropriate ceremonies the completion of one hundred years of honorable and useful service; and liberal appropriations by Congress for rebuilding and extending the institution will enable it to begin its second century with the well-founded hope of larger and long-continued usefulness.

In the event of remaining vacancies in the grade of second lieutenant in any year further appointments are made, (2) from among the enlisted men of the army who are authorized by law to enter a competitive examination, after two years' service, provided they be between the ages of 21 and 30, unmarried, and physically and morally qualified. To obtain a commission the candidate must pass an educational and physical examination before a board of officers. The board also takes into consideration the character, capacity, and military record of the candidate. Many well-educated young men, unable to obtain appointments to West Point, enlist in the army for the express purpose of becoming officers through this medium. And (3) civilians are appointed to vacancies that may be left when the two first classes have been exhausted. To be eligible for appointment the candidate must be a citizen of the United States, unmarried, between the ages of 21 and 27 years, and must be approved by an examining board as to habits, moral character, physical ability, education, and general fitness for the service.

Although the military academy has in the past supplied a majority of the officers entering the service in each year, the partial increase of the army in 1898 by reason of the breaking out of hostilities with Spain, and resulting casualties, and its re-organization with increased numbers on the disbandment of the volunteer army called into service during the Spanish-American war, has necessitated the appointment of a large number of officers from among the enlisted men, volunteers, and civilians. Of the ap-

pointments to the line of the army in the four years following the Spanish-American War, about one-sixth were supplied by the military academy; the others having been appointed from the ranks, civil life, and from the volunteers of the war with Spain and in the Philippines. The volunteers and enlisted men had acquired useful experience and were selected on the ground of their military conduct and intelligence, yet this considerable influx in the commissioned personnel had not permitted of a systematic military education. To overcome this deficiency, and with a view to maintaining a high standard of instruction and general training of the officers of the army, and to keep pace with the difficulties of the problems involved in transporting, supplying, and handling armies of modern times, and for caring for and rendering effective the increasing complexity of the machines and material used in the defense of the coast fortifications, a system of military instruction is required, and accomplished through officers' schools at each military post, for elementary instruction in theory and practice, and at special service schools — (a) The Artillery School at Fort Monroe, Va.; (b) The Engineer School of Application, Washington Barracks, D. C.; (c) The School of Submarine Defense, Fort Totten, N. Y.; (d) The School of Application for Cavalry and Field Artillery at Fort Riley, Kansas; (e) The Army Medical School. A General Service and Staff College is also maintained at Forth Leavenworth; and a War College, at the city of Washington, for the most advanced instruction in the military art and science. The Congress has made provision for the maintenance of these schools, and given its sanction to the general system of military education prescribed therein.

Promotions in the line are made through the whole army by seniority, in the several arms, namely, artillery, cavalry, and infantry, respectively, between first lieutenant and brigadier-generals, relative rank being determined by length of service as an officer of the United States either in the regular or volunteer forces. Promotions among officers of the staff holding permanent commissions are made in like manner in the several departments and corps, respectively.

Educational and physical examinations are required of officers of the line upon promotion between the grades of first lieutenant and majors.

In every service, to maintain a reasonably low age among the persons actively employed, it is essential that some scale be fixed for the retirement of old and worn-out officers, and those incapacitated for active military service. When an officer in the line of promotion is retired from active service, or in the event of casualties, by reason of retirements, resignations, or deaths, the next officer in rank is promoted to his place, and the same rule of promotion is applied successively, to the vacancies consequent upon such casualties.

The laws for the retirement from the military service provide:

(1) If an officer has had 30 years' service (and makes application therefor), or if he has reached the age of 62, he *may* be placed on the retired list.

(2) If an officer has been borne on the army register for 40 years (and makes application therefor), or if he has reached the age of 64, he *shall* be retired from active service.

(3) An officer may also be retired on account of disability contracted in the line of duty; or, *wholly* retired, if his incapacity is not the result of an incident of service, and his name dropped from the rolls of the army.

(4) In like manner enlisted men of the army may be retired after 40 years of service.

Officers and enlisted men on the retired list receive 75 per cent of the pay of the rank held upon retirement, but they are withdrawn from command and promotion, except, that officers may be assigned to duty as military instructors at colleges, and at the Soldiers' Home (D. C.). They are, however, amenable to the rules and articles of war, and subject to trial by court-martial for a violation thereof.

The Staff of the Army.— The Secretary of War is the head of the War Department, and performs such duties as are required of him by law, or may be enjoined upon him by the President concerning the military establishment and administers its affairs and promulgates the orders and directions of the President through a chief of staff, who has, under the Secretary of War, supervision of all troops of the line and of the administration of the several staff departments. The Secretary of War is charged with the supervision of estimates of appropriations, of all purchases of army supplies, of all expenditures for the support, transportation, and maintenance of the army; and such expenditures of a civil nature as may be placed by Congress under his direction. He also has supervision of the Military Academy and of military education in the army, of the Board of Ordnance and Fortification, of the various battlefield commissions. He has charge of all matters relating to national defense and seacoast fortifications, army ordnance, river and harbor improvements, etc. He also has charge of the establishment or abandonment of military posts, and of all matters relating to lands under the control of the War Department. His duties also embrace all matters pertaining to civil government in the island possessions subject to the jurisdiction of the War Department.

But twice in the history of military legislation has provision been formally made for the office of Chief of Staff of the Army: (1) in the act of 3 March 1813, which has never been repealed in express terms, and (2) in the act of 3 March 1865, repealed by the act of 3 April 1869.

While legislative sanction is not required to enable the President to assign an officer to duty as Chief of Staff, a position demanded by the necessities of the service, Congress, by the act of 14 Feb. 1903, formally authorized the office and declared that under the direction of the President or the Secretary of War, that the Chief of Staff shall have supervision of all troops of the line and of the Adjutant-General's, Inspector-General's, Judge Advocate's, Quartermaster's, Subsistence, Medical, Pay and Ordnance Department, the Corps of Engineers, and the Signal Corps.

It is required of the general staff under the law, to prepare plans for the national defense

and for the mobilization of the military forces in time of war; to investigate and report upon all questions affecting the efficiency of the army and its state of preparation for military operations; to render professional aid and assistance to the Secretary of War and to general officers and other superior commanders, and to act as their agents in informing and co-ordinating the action of all the different officers who are subject to the supervision of the Chief of Staff and to perform such other military duties, not otherwise assigned by law, as may be, from time to time, prescribed by the President or the Secretary of War.

With respect to the staff the tendency has been to fill its offices from the line, and this prevails at this day, except in the Medical Department (which is open to appointment from civil life, after examination as to professional capacity) and the chaplains; but since 1851, when the regular law of promotion was secured to each of them, it has been necessary that a newcomer should enter at the foot of the list, except indeed he entered at its head, as Generals Johnston and Meigs did in the Quartermaster's Department; but that was in the days when all general officers were selected from the army at large. At present the law confines the selection to the chiefs of departments.

Having in view especially the duties to be performed by regular officers in connection with the volunteer force, a system of detail from the line of the army has been provided for (which in a measure abolishes the permanent staff), in order to give a training for as many officers as possible in a variety of experience which will fit them for the duties of the staff and regular command in the combined force of regulars and volunteers.

In time of peace the military administration of the army is conducted by the Secretary of War through the Chief of Staff and the several bureaus; and the country is divided into military geographical departments, which is similar to the command of a separate army, with the same powers and duties in similar cases over all the troops within the limits of the department. The commander is assigned to duty by the President, who alone can relieve him, and who also fixes the limits or boundaries of the command.

In time of war, military forces are organized into armies, corps, divisions and brigades; and for each (as well as the commander of a military department) is provided a competent administrative staff, which is allied in its personnel and duties to the staff for the whole army, which is outlined below:

ORGANIZATION OF THE STAFF OF THE U. S. ARMY.

	Major-Generals.	Brigadier-Generals.	Colonels.	Lieutenant-Colonels.	Majors.	Captains.	First Lieutenants.	Second Lieutenants.	Ordnance Sergeants.	Post Commiss'y Sergts.	Post Q. M. Sergeants. * Sec. 26 of the act of 2 Feb. 1901, provides, "that so long as there remain any officers holding permanent appointments in the Adjutant-General's Department, the Inspector-General's Department, the Quartermaster's Department, the Subsistence Department, the Pay Department, the Ordnance Department, and the Signal Corps, including those appointed to original vacancies in the grades of captain and first lieutenant under the provisions of sections sixteen, seventeen, twenty-one, and twenty-four of this act, they shall be promoted according to seniority in the several grades, as now provided by law, and nothing herein contained shall be deemed to apply to vacancies which can be filled by such promotions or to the periods for which the officers so promoted shall hold their appointments; and when any vacancy, except that of the chief of the department or corps, shall occur, which can not be filled by promotion as provided in this section, it shall be filled by detail from the line of the Army, and no more permanent appointments shall be made in those departments or corps after the original vacancies created by this act shall have been filled. Such details shall be made from the grade in which the vacancies exist, under such system of examination as the President may from time to time prescribe.

"All officers so detailed shall serve for a period of four years, at the expiration of which time they shall return to duty with the line, and officers below the rank of lieutenant-colonel shall not again be eligible for selection in any staff department until they shall have served two years with the line.

"That when vacancies shall occur in the position of chief of any staff corps or department the President may appoint to such vacancies, by and with the advice and consent of the Senate, officers of the Army at large not below the rank of lieutenant-colonel, and who shall hold office for terms of four years. When a vacancy in the position of chief of any staff corps or department is filled by the appointment of an officer below the rank now provided by law for said office, said chief shall, while so serving, have the same rank, pay, and allowances now provided for the chief of such corps or department. And any officer now holding office in any corps or department who shall hereafter serve as chief of a staff corps or department and shall subsequently be

The Adjutant-General promulgates all orders of a military character of the President, and the Secretary of War, and conducts the general correspondence of the army; receives reports and returns; prepares commissions, appointments, and acceptances of resignations for issuance; and has charge of the recruiting service.

The Inspector-General, with his assistants, inspects all military commands and stations, the schools of application, the military departments of all colleges and schools at which officers of the army are detailed, all depots, rendezvous, armories, arsenals, fortifications, and public works of every kind under charge of or carried on by officers of the army; and also the money accounts of all disbursing officers of the army.

The Quartermaster-General, aided by assistants, provides transportation for the army; also clothing and equipage, horses, mules, and wagons, vessels, forage, stationery, and other miscellaneous quartermaster stores and property for the army, and clothing and equipage for the militia; constructs necessary buildings, wharves, roads, and bridges at military posts, and repairs the same; furnishes water, heating and lighting apparatus; pays guides, spies, scouts, and interpreters, and is in charge of national cemeteries.

The Commissary-General of Subsistence has administrative control of the Subsistence Department; the disbursement of its appropriations; the providing of rations and their issue to the army; the purchase and distribution of articles authorized to be kept for sale to officers and enlisted men; the administrative examination of accounts of subsistence funds preliminary to their settlement by the proper accounting officers of the Treasury; and the examination and settlement of returns of subsistence supplies.

The Surgeon-General is charged with the administrative duties of the Medical Department; the designation of the stations of medical officers, and the issuing of all orders and instructions relating to their professional duties. He directs as to the location, purchase, and distribution of the medical supplies to the army. The Army Medical Museum and the official publications of the Surgeon-General's office are also under his direct control.

The Paymaster-General is charged with the payment of the officers and enlisted men of the army and civil employees of the Department; with furnishing funds to his officers and seeing that they duly account for the same, and with a preliminary examination of their accounts; also with the payment of Treasury certificates for bounty, back pay, etc., and balances due deceased officers and soldiers of the Volunteer and Regular army.

The Chief of Engineers is charged with all duties relating to construction and repair of fortifications, whether permanent or temporary; with all works of defense; with all military roads and bridges, and with such surveys as may be required for these objects, or the movement of armies in the field. It is also charged with the river and harbor improvements, with military and geographical explorations and surveys, with the survey of the lakes, and with any other engineer work specially assigned to the corps by acts of Congress or orders of the Secretary of War.

The duties of the Chief of Ordnance consist in providing, preserving, distributing, and accounting for every description of artillery, small arms, and all the munitions of war which may be required for the fortresses of the country, the armies in the field, and for the whole body of the militia of the Union. In these duties are comprised that of determining the general principles of construction and of prescribing in detail the models and forms of all military weapons employed in war. They comprise also the duty of prescribing the regulations for the proofs and inspection of all these weapons, for maintaining uniformity and economy in their fabrication, for insuring their good quality, and for their preservation and distribution.

The Judge-Advocate-General is directed by law to "receive, review, and cause to be recorded the proceedings of all courts-martial, courts of inquiry, and military commissions." He also furnishes the Secretary of War information and advice relating to lands under control of the War Department, and reports and opinions upon legal questions arising under the laws, regulations, and customs pertaining to the army, and upon questions arising under the civil laws; reports upon applications for clemency in the cases of military prisoners; examines and prepares legal papers relating to the erection of bridges over navigable waters; drafts bonds, and examines those given to the United States by disbursing officers, colleges, and others; examines, revises, and drafts charges and specifications against officers and soldiers; and also drafts and examines deeds, contracts, licenses, leases, and legal papers generally.

The Chief Signal Officer is charged with the supervision of all military signal duties, and devices connected therewith, including telegraph and telephone apparatus and the neces-

---

retired, shall be retired with the rank, pay, and allowances authorized by law for the retirement of such corps or department chief: *Provided*, That so long as there remain in service officers of any staff corps or department holding permanent appointments, the chief of such staff corps or department shall be selected from the officers so remaining therein."

a. Assistant surgeons have the rank, pay, and emoluments of First Lieutenants of Cavalry for the first five years' service, and the rank, pay, and emoluments of the grade of captain after five years' service. (Sec. 4, Act 23 June 1874.)

b. By the Act of 3 March 1873, the Secretary of War is authorized to select from the sergeants of the line of the Army, who shall have faithfully served therein five years, three years of which in the grade of non-commissioned officer, as many Commissary Sergeants as the service may require, not to exceed one for each military post or place of deposit of subsistence supplies.

c. By the Act of 5 July 1884, the Secretary of War is authorized to appoint as many Post Quartermaster Sergeants as he may deem necessary for the interests of the service, not to exceed eighty, to be selected by examination from the most competent enlisted men of the Army who shall have served at least four years. The act of 8 July 1898, increased the number of Post Quartermaster Sergeants to one hundred and five; and the Act of 2 Feb. 1901, further increased the number to one hundred and fifty.

d. The Act of 1 March 1887, organizing the Hospital Corps provides that it shall consist of Hospital Stewards, Acting Hospital Stewards, and Privates, and that it shall be permanently attached to the Medical Department, and shall not be included in the effective strength of the Army nor counted as a part of the enlisted force provided by law.

e. The Act of 2 Feb. 1901, provides for three battalions of engineer troops, and although commanded by listed force is included in the strength of the line of the Army.

sary meteorological instruments for use on target ranges and other military uses; the construction, repair, and operation of military telegraph lines, and the duty of transmitting information for the army by telegraph or otherwise, and all other duties usually pertaining to military signaling.

The Chief of the Record and Pension Office is charged by law with the custody of the military and hospital records of the volunteer armies and the transaction of the pension and other business of the War Department connected therewith, including the publication of the Official Records of the War of the Rebellion.

Organization of the Line of the Army.— Each regiment of cavalry consists of 12 troops and one band, organized into 3 squadrons of 4 troops each, and under the minimum requirements of the law is constituted as follows:

For each regiment: 1 colonel and 1 lieutenant-colonel, 1 chaplain, and 2 veterinarians. The non-commissioned staff consists of a regimental sergeant-major, 1 quartermaster-sergeant, 1 commissary-sergeant, and 2 color sergeants. Three additional captains and 3 first and second lieutenants, being authorized beyond the requirements of the troops, are available for detail as regimental and squadron adjutants, quartermasters and commissaries. For each troop: 1 captain, 1 first and 1 second lieutenant, the enlisted force consisting of 1 first sergeant, 1 quartermaster-sergeant, 6 sergeants, 6 corporals, 2 cooks, 2 blacksmiths and farrier, 1 saddler, 1 wagoner, 2 trumpeters, and 43 privates. A major commands each squadron, for which a staff consisting of an adjutant (1st lieutenant) and quartermaster and commissary (2d lieutenants) and 1 sergeant-major is authorized.

The regimental organization of the artillery arm has been discontinued, and it is constituted and designated as the Artillery Corps, comprising two branches, namely: The Coast Artillery, defined by law as that portion charged with care and use of the fixed and movable elements of land and coast fortifications, including submarine mine and torpedo defenses; and the Field Artillery, as that portion accompanying an army in the field, and including field and light artillery proper, horse artillery, siege artillery, mountain artillery, and also machine-gun batteries.

The Artillery Corps consists of a chief of artillery selected and detailed by the President from among the colonels of artillery to serve as a member of the General's staff, his duties being prescribed by the Secretary of War; 14 colonels (one of whom shall be chief of artillery, with the rank of brigadier-general), 13 lieutenant-colonels, 39 majors, 195 captains, 12 chaplains, 195 first lieutenants, 195 second lieutenants (surplus captains and lieutenants not required for duty with batteries or companies being available for duty as staff officers of the various artillery garrisons, and other details); 21 sergeants-major senior grade, and 27 sergeants-major junior grade; 1 electrician-sergeant is authorized for each coast artillery post having electrical appliances; 30 batteries of field artillery, 126 batteries of coast artillery, and 10 bands constitute the strength of an artillery force not to exceed 18,920 men, the enlisted strength of the companies being fixed by the President according to the requirements of the service.

The enlisted strength authorized (24 Oct. 1902) for each field battery is as follows:

One first sergeant, 1 quartermaster-sergeant, 1 stable-sergeant, 6 sergeants, 12 corporals, 2 cooks, 4 artificers, 2 musicians, 91 privates; and for each company of coast artillery: 1 first sergeant, 1 quartermaster-sergeant, 8 sergeants, 12 corporals, 2 cooks, 2 mechanics, 2 musicians, and 81 privates.

The United States, as far back as 1886, recognizing the necessity for providing modern seacoast defenses to protect the cities and harbors, adopted a policy of liberal appropriations for seacoast defense, and to carry out a general plan for the continuing appropriations made available, passed a law creating a board of ordnance and fortification whose duty it is «to make all needful and proper purchases, experiments, and tests to ascertain, with a view to their utilization by the government, the most effective guns, small arms, cartridges, projectiles, fuses, explosives, torpedoes, armor plate, and other implements and engines of war.» The membership of this board comprises the lieutenant-general commanding the army (who is its president), one officer each from the corps of engineers and the ordnance department, two from the artillery, and one civilian.

Each regiment of infantry consists of 12 companies and 1 band, organized into 3 battalions of 4 companies each, and under the minimum requirements of the law is constituted as follows: For each regiment 1 colonel and 1 lieutenant-colonel and 1 chaplain. The non-commissioned force consists of a regimental sergeant-major, 1 quartermaster-sergeant, 1 commissary-sergeant, and 2 color-sergeants. Three additional captains and 3 additional first and second lieutenants, being authorized beyond the requirements of the companies, are available for detail as regimental and squadron adjutants, quartermasters, and commissaries. For each company, 1 captain, 1 first and 1 second lieutenant, the enlisted force consisting of 1 first sergeant, 1 quartermaster-sergeant, 4 sergeants, 6 corporals, 2 cooks, 2 musicians, 1 artificer, and 48 privates.

The President is also authorized to enlist «when in his opinion the conditions in the Philippine Islands justify such action» not to exceed 12,000 natives of those islands for service as scouts, with such officers as shall be deemed necessary, and organize them into troops, companies, squadrons, and battalions, but this force shall be included in the maximum enlisted strength of 100,000 for the whole army. Accordingly, there have been enlisted and there are now in service (15 Oct. 1902), about 5,000 Philippine Scouts. A provisional regiment of native Porto Ricans is also maintained. The field officers are selected from officers of the next lower grade in the regular army, the company and regimental and staff officers being selected by the President. The strength of the regiment on 15 Oct. 1902 was 29 officers and 840 enlisted men.

Militia.— The militia becomes national only when called into the actual service of the Federal government. The Constitution makes it the duty of Congress «to provide for organizing, arming, and disciplining the militia,» and «for

calling forth the militia to execute the laws of the Union, suppress insurrections, and repel invasions." Though the necessity for a well-regulated militia to the security of a free state is recognized by the Constitution, the arguments and the logic of facts have alike failed to secure that attention demanded by the gravity of the subject prior to the act of 21 Jan. 1903, which brings the militia laws to conform to modern requirements for efficiency and effectiveness, although repeated efforts have been made to accomplish this result from the day of Washington.

The military reserve of the United States is more than 10,000,000 men, but the volunteer organizations maintained in the States have not in the past (1902) exceeded 100,000 men.

The President is Commander-in-Chief of the militia of the several States when called into the actual service of the United States; and is empowered to call out these forces in event of invasion, actual or imminent, and in cases of insurrection or rebellion against the authority of the United States or any one of the States thereof, for a term of service not exceeding nine months. While so employed the troops receive the pay, rations, etc., of regular soldiers, are subject to the Rules and Articles of War, and their officers take precedence in rank next after officers of like grade in the regular service, or in such volunteer organizations as may also be in the service of the United States. The appointment of the officers (to the grade of brigadier-general) and the authority for training the militia according to the discipline prescribed by Congress are expressly reserved to the respective States.

The relations of the National Guard, however, to the Federal government have never been defined or settled. The confusion, controversy, and bad feeling arising from this uncertain status have been made painfully apparent during the Civil War, and at the beginning of the war with Spain.

The militia is capable of being utilized, first, as active militia when called out by the President for the specific purposes enumerated in the Constitution; second, as an already organized volunteer force when its organizations respond as such to calls for volunteers for general military purposes under authority of Congress; and, third, as the great school of the volunteer soldier, the benefits of which are received by the country when the members of the guard respond individually to calls for volunteers.

Under the militia law the regularly enlisted, organized, and uniformed active militia (popularly known as the National Guard) in the several States and Territories and the District of Columbia, constitute the organized militia of the United States; and provides that the organization and discipline thereof shall conform with that provided for the regular and volunteer armies; and contemplates establishing closer relations and better co-operation between the National Guard and the regular army, and to promote the general efficiency and dignity of the Guard as a part of the military system of the United States.

To aid in accomplishing these objects, the law provides that the general government shall furnish to the Guard the same arms which it furnishes to the regular army, and for the voluntary participation by the Guard with the regular army in maneuvers and field exercises for brief periods in each year. The law also contains provisions making the National Guard organizations which choose voluntarily to go beyond the limitations of militia service in effect a first volunteer reserve. It also provides for ascertaining by practical tests, in advance of a call for volunteers, the fitness to hold volunteer commissions, of members of the National Guard, graduates of the military schools and colleges, and other citizens with military training, thus constituting an eligible list from which in case of a call for volunteers officers may be taken.

The military forces of the United States are, therefore, as follows:

1. A regular army, capable of enlargement by the President when he sees war coming, to 100,000 men.

2. Such of the organized militia, trained as National Guard, as the President shall see fit to call into the service of the United States.

3. Such other volunteers as Congress may deem necessary to call forth from the States according to the respective quotas. See GENERAL STAFF OF THE ARMY.

H. C. CORBIN,
Major-General and Adjutant-General, U. S. A.

Army and Navy Maneuvers. The object of maneuvers is to train, in time of peace, the fighting forces of a nation by handling them, as far as practicable, as in time of war, the forces designated being divided, for this purpose, into two opposing bodies. Previous military training, or drill, is presupposed. Maneuvers are of three kinds: First, Land maneuvers, taking place entirely on land; second, Naval maneuvers, where fleets maneuver against fleets; third, Combined army and navy maneuvers. The last two are of comparatively recent origin.

European Maneuvers.— In the days of the old French monarchy, previous to the Revolution, the necessity for practice in handling large bodies of troops became apparent, and under Louis XIV. and Louis XV. large camps of instruction were instituted in France, then the leading military nation of the world. In these camps troops of all arms were concentrated for practice in field and siege warfare. Maneuvers are now annually held in all the principal countries of Europe. Prussia was the first country to follow the lead of France, and as in no other country than in Germany have they reached a higher development the German maneuvers will be taken as a type. They are the culmination and test of the military instruction of the year. As in almost all countries where military service is compulsory, the annual contingent of conscripts drawn for service is called to the colors in the autumn. Beginning with individual instruction, a progressive system of military training is carried on until the following summer, by which time the troops have been thoroughly drilled and are ready for the maneuvers. As operations in the grand maneuvers are carried on over a large extent of territory, the time fixed is after the crops are harvested so that agricultural interests are interfered with as little as possible. The annual maneuvers begin with regimental and brigade exercises for the infantry, with battalion exercises for field artillery (a battalion consists of two or more batteries) and with special maneuvers for cavalry. Maneuvers are also carried on

all over the country by the army corps not participating in the grand maneuvers. The programme for the grand maneuvers is carefully worked out beforehand by the Great General Staff at Berlin. When the maneuvers of one year are over, work is begun on the scheme of those for the next year. Staff officers are sent out to select the ground, which is changed from year to year so that the terrain may be varied and the interests of the inhabitants may be considered. Districts where there are vineyards or growing autumn crops are generally avoided. The troops to take part are selected and depots of supplies at convenient points in the theatre of operations are provided for. Foreign officers of distinction, and especially the foreign military attachés, are invited to attend. They are during the maneuvers the guests of the emperor. Officers are specially detailed to accompany them. They are furnished with plans of operations, with maps, and with all other necessary information. In the grand maneuvers a large body of troops of all arms always takes part; often as many as four army corps, seldom less than two. In 1901, for instance, the forces comprised two army corps, with some additional regiments of infantry from other corps, two divisions of cavalry, and 538 guns, including horse artillery, light artillery, field howitzers and machine guns; altogether about 75,000 men and 18,000 horses. (In the grand maneuvers in France in 1901, which were witnessed by the Czar of Russia, about 140,000 troops took part.)

The supreme control of the grand maneuvers is exercised by a director of maneuvers, who is frequently the emperor himself. Several officers of high rank are designated as umpires. Their duty is to watch all the operations carefully, observe mistakes and estimate results. They decide, for instance, whether a certain attack was properly made, and whether or not it was successful. They direct to be temporarily withdrawn from action a unit supposed to be disabled or captured. In actual war this would not be necessary, but in simulated war, where blank cartridges are used, no one on either side is hurt and the opposing lines come within close distance of each other without loss of numbers and with their nerves unshaken. It is therefore necessary to have expert disinterested judges to decide what the losses would have been, to what extent the morale of the troops might have been impaired, and what the results of the conflict would have been had it been a real and not an imaginary battle.

The time for concentration having arrived, the troops designated proceed to their rendezvous by marching or by rail. In 1901 the first corps marched nearly 200 miles at an average rate of 23 miles a day. As the railroads are under government control, all arrangements for transportation of troops and supplies are easily made so that regular traffic is interfered with but little. No tents are carried, the troops being billeted on the inhabitants at prescribed rates or going into bivouac. Large wagon trains are therefore not needed. What wagons are required to carry supplies from the depots to the troops are requisitioned in the district. The troops are in heavy marching order and carry their heavy packs without fatigue. This is because they are trained to it, habitually carrying their packs in all military exercises throughout the year. The concentration having been effected, the troops are organized into two armies, each with a general in command selected by the emperor. For convenience, each army is given a temporary designation, as the Red Army, the Blue Army.

A general war situation is announced. The Red Army is supposed to be an invading army and to advance across the frontier with some important city as an objective. The Blue Army is on the defensive. The armies are at the beginning many miles apart, the whole theatre of operations covering perhaps 60 or 70 miles square. Each commanding general makes his dispositions, posts his troops, and issues such orders as he thinks necessary. Beyond a knowledge of the general scheme, he knows nothing about the movements or location of the enemy except what he finds out from reconnoissances, spies, etc., as in actual war. At the end of the first day's operations the results are determined by the director and the umpires and the general situation is summed up. The work of the day is criticised and, if necessary, the director gives the generals in command additional instructions for the following day. Each general then goes on with his plan or modifies it according to his instructions or the developments of the day, and issues his orders for the next day; and so on throughout the maneuvers. To describe clearly the operations day by day in detail throughout the maneuver period is impracticable without the assumption of a concrete case and the use of maps, so it will not be attempted. A feature of the maneuvers is often a charge upon infantry in position by the combined cavalry force. This is somewhat spectacular and would probably not be done under similar circumstances in war, but this fact is recognized by all concerned and the operation is therefore not misleading. It gives an opportunity to show the training of the cavalry and how it can be handled in large masses. As the director of maneuvers has absolute control of both sides, he can arrange the problems so that the maneuvers shall take place in the exact localities desired. The question of the location of supply depots at convenient places beforehand is therefore an easy one.

A large captive signal balloon accompanies the emperor's headquarters. It is distinguished from other captive balloons by a special flag. Signals are made by attaching to the balloon combinations of balls and inflated bags. These signals are known to all, can be seen for great distances and consequently orders can thus be transmitted to all the troops more quickly than in any other way yet devised.

Great attention is paid to sanitary conditions and in consequence the percentage of sickness is very small. Formerly in maneuvers much sickness prevailed among the troops due to the use of impure water. To guard against this a careful inspection of the water supply of the region is made beforehand, and placards are put up showing where water is to be had and its condition.

These maneuvers are of great value in training officers, especially staff officers. They also serve as a sort of examination for officers, whose work in the field comes under the observation of their superiors, from the emperor down. Officers showing zeal and ability are marked for advancement, while those whose work does not

come up to the standard are reproved or even more severely dealt with, officers whose handling of their men does not suit the emperor being often relieved from their commands. The maneuvers are terminated by a grand review before the emperor, all the troop taking part, after which they return to their garrisons.

American Maneuvers.— In the United States circumstances have heretofore prevented the carrying on of maneuvers as in Europe. Our army was so small and so widely scattered that a large enough force to make it worth while could not be brought together without great inconvenience and expense. Maneuvers on a small scale were had in Indian Territory in 1889, in which troops stationed within marching distance took part, but they were not again attempted until 1902, when the first of what it is hoped will be an annual series took place They marked, too, for the first time in the United States the participation of the National Guard in conjunction with regulars. In order to give a clear idea of how they are managed in the United States it will be best to give a brief account of the maneuvers of that year. They will be improved upon and developed as time goes on, but the work done then will serve as a basis. The place selected was the large military reservation of Fort Riley, Kansas. The department commander was selected to direct them. A board of officers was convened at Omaha beforehand to draw up plans for the maneuvers and rules for their conduct. Besides the garrison of Fort Riley, troops were ordered from posts in Kansas, Nebraska, Arkansas and Oklahoma. The troops from Arkansas and Oklahoma went by rail; the others marched. Marches were conducted with all the precautions that would be necessary in an enemy's country. The force collected comprised a battalion of engineers, three regiments of infantry, three squadrons of cavalry, five batteries of field artillery and detachments of the Signal and Hospital Corps. Invitations were sent by the war department to the governors of States to send National Guard troops to take part in the maneuvers. As the necessary expense was not at that time borne by the government, only two States, Kansas and Colorado, sent troops: the former, two regiments; the latter, one battalion. Many National Guard officers, however, were sent from their States as observers. Foreign military attachés were also invited. The troops had both blue and khaki uniforms. When divided into opposing forces, one wore blue, the other khaki, and they were designated as the Blues and the Browns, respectively. An officer was named as chief umpire, with a number of other officers as his assistants, one being chief umpire for the Blues; another, chief umpire for the Browns. A decision of an umpire on any point must be observed, but if any officer concerned should think it a wrong one, he could appeal from it after the maneuver. The rules provided that firing should cease when opposing forces came within one hundred yards of each other, and that cavalry charges should stop at the same distance. The greatest care was taken to see that no ball cartridges were carried by the men. Men supposed to be wounded were immediately taken care of by the Hospital Corps. Connection by telegraph and telephone was established and maintained by the Signal Corps. Poles were set up and wire strung as fast as troops marched, and any part of a force could be kept constantly in communication with any other part or with headquarters. A smoke signal bomb, which could be seen for long distances, was sent up at the conclusion of the operations each day and the troops were then marched back to their camps. The programme for the maneuvers provided for a series of military problems, varying in character from day to day, each being completed in one day. As the National Guard contingent did not arrive as soon as the regulars, they took no part in the operations of the first few days. There were nine problems during the maneuvers. Some of them will be briefly stated. In the descriptions "battalion" signifies a battalion (four companies) of infantry or engineers; "squadron", a squadron (four troops) of cavalry.

Problem 1. "The Blues represent the outposts of an army corps on the defensive, holding Fort Riley. Strength: 9 battalions, 1 squadron, 3 batteries. They are placed from right to left as an outpost line. The guns occupy commanding positions in the line and are sheltered by gun-pits constructed after their arrival in position. The line selected was judged very satisfactory and the time made excellent as the Blues marched three miles and then established their line four miles long in two hours and a half, the ground being heavy and the roads muddy. The Browns represent two reconnoitering parties of an advancing army corps. The first consists of 1 battalion, 1 squadron, 1 battery; the second of 1 squadron, and 1 battery. Approaching from different directions, they have orders to unite near Fort Riley for a demonstration against the enemy's position in order to ascertain his strength. The Brown batteries were ordered to locate and engage the hostile batteries. One opened fire at 3,000 yards. The other, through an error, came under fire, in column, at 1,400 yards. As the hostile batteries were under shelter while the Browns were in the open, the umpires decided that both Brown batteries had been put out of action. They also decided that the Brown infantry and cavalry were not handled aggressively enough for a reconnoissance in force, that the strength of the Blues had not been fully developed, and that the information gained by the Brown commander as a result of the reconnoissance would consequently have been misleading. The results of the day were in favor of the Blues.

Problem 2. Attack and defense of a convoy. The Blue army is operating about 50 miles southwest of Topeka, with that point as a base. The railroads are assumed to be broken up and supply by wagon train is necessary. One of the trains, consisting of 180 wagons, has camped about 25 miles from Topeka. A raiding force of the Browns has gotten in rear of the main Blue army. Its commander has learned of the train and plans its capture or destruction. The Blue escort consists of 6 battalions, 1 battery, 2 troops; the train is in two divisions. The commander expects to be attacked and moves out with advance and rear guards and with a half battalion on each flank of each division of the train. The remainder of his force, 2 battalions and 1 battery, is between the two divisions. The commander has orders to push on as rapidly as possible as the supplies are badly needed. The Brown raiding force consists of a platoon of artillery and 10 troops of cavalry. The op-

posing forces having come in contact, a series of detached actions ensue, the result being that the Browns are finally driven off after having destroyed 36 wagons. This is due to faulty disposition of the train, it having been, at one point, unnecessarily exposed to hostile artillery fire. With this exception the Blues were adjudged to have been in the main well handled. The Browns were criticised for not having thoroughly informed themselves of the enemy's dispositions, in consequence of which a portion of their force came unexpectedly upon a largely superior force of the enemy and was declared out of action. A charge was also made upon infantry in position, which should not have been done. Had the Browns, with their inferior force, acted with more caution, they could have kept up their harassing tactics and in the end have inflicted much more damage on the train.

Problem 3. This consisted of three separate exercises, each embracing the employment of a regiment as an outpost for an imaginary larger command. In each case the outpost was established by a regular regiment, National Guard officers accompanying the commander as spectators. Each outpost, when completely established, was relieved by a National Guard regiment. When a National Guard outpost was established a small force of regulars, representing an outlined enemy, attacked and the outpost made the necessary preparations for defense. For the instruction of the National Guard, great care was taken to explain the function of an outpost and the manner of receiving the attack. It was also explained that the attacking force was supposed to be superior in strength to the outpost. In the execution of these exercises the criticism was made that the tendency of the men was to hold on to their advanced positions too long, the idea of retreat being repugnant. Such a retreat, however, would have been necessary had the simulated attack been real, and in this case it was necessary for carrying out the exercise ordered. The object of the exercise, which was often lost sight of, was not to maintain a line of outposts under attack, but to show how entire outposts could be brought into united defensive action in order to give the main body time to make its dispositions. The unanimous opinion of the umpires was that the employment of a small number of men to represent a large imaginary force is unsatisfactory, and should be discontinued in future maneuvers. The situation is unreal and it is difficult to make the participants realize it.

In the evenings the officers were assembled and the events of the day were discussed. The board appointed to draw up plans for the maneuvers agreed that the most desirable form is that employed in Europe, where two large bodies, each operating from a definite base, move forward in the execution of a large strategical problem, occupying several days and covering a large extent of country. All the features of an active campaign are introduced and all the elements of tactics are brought in, but circumstances prevent it in the United States, as the necessary ground is not available within reasonable distances. The general prevalence of fences, which in agricultural districts of continental Europe are absent, prevent free movement over ground not owned by the government and their destruction or removal would be too expensive. The general opinion after the maneuvers was that they were instructive and valuable in the highest degree and were well worth the cost. The conditions of actual warfare were well maintained and show features were entirely eliminated.

Permanent Drill Grounds.— The Act of Congress of 2 Feb. 1901, authorized the secretary of war "to cause preliminary examinations and surveys to be made for the purpose of selecting four sites with a view to the establishment of permanent camp grounds for instruction of troops of the regular army and National Guard, with estimates of the cost of the sites and their equipment with all modern appliances, and for this purpose is authorized to detail such officers of the army as may be necessary to carry on the preliminary work." In accordance with this act four sites were selected, regard being had to geographical conditions, so that they would be available for as large a part of the army and militia throughout the United States as possible without undue expense for transportation of troops and supplies. The Militia bill, which became a law 21 Jan. 1903, contained the following provisions: "That the secretary of war is hereby authorized to provide for participation by any part of the organized militia of any State or Territory on the request of the governor thereof in the encampment, maneuvers and field instruction of any part of the regular army at or near any military post or camp or lake or seacoast defenses of the United States. In such case the organized militia so participating shall receive the same pay, subsistence, and transportation as is provided by law for the officers and men of the regular army, to be paid out of the appropriation for the pay, subsistence, and transportation of the army." "That whenever any officer of the organized militia shall, upon recommendation of the governor of any State, Territory, or general commanding the District of Columbia, and when authorized by the President, attend and pursue a regular course of study at any military school or college of the United States such officer shall receive from the annual appropriation for the support of the army the same travel allowances, and quarters, or commutation of quarters, to which an officer of the regular army would be entitled if attending such school or college under orders from proper military authority, and shall also receive commutation of subsistence at the rate of one dollar per day while in actual attendance upon the course of instruction." Congress having recognized the value of maneuvers and having made provision for them to be carried on, they may now be considered a permanent feature of our military system. The armed land forces of the country, regulars and militia, will hereafter be trained in practical military work together as they never have been in years gone by and the outbreak of another war should find the country better prepared to meet it than at any previous time in its history.

Naval Maneuvers may be tactical or strategical; the former having to do with the handling of fleets when they are within sight of each other, the latter when they are not. As all the elements, such as size and speed, character and arrangement of armor, number and power of guns, of different classes of ships, battleships, cruisers, and torpedo boats, are well

known, it is supposed, when they come in conflict, that the result will be a foregone conclusion, assuming the personnel to be of equal quality. The personal element, the man behind the gun, while of vital importance in war, is a factor that cannot be easily estimated in naval maneuvers. Much more attention is therefore given to strategical maneuvers. A fleet going out for maneuvers is divided into two squadrons, one to attack, the other to defend. A passive defense is not contemplated. While the object may be the defense of a harbor, the way to accomplish it is not to wait in port for the enemy, but to go out to seek him on the open sea. Otherwise the advantage of one of the most valuable characteristics of ships, their mobility, would be lost. A common form of strategical problem is to assign to the offense (Red squadron) the task of seizing and holding some harbor within a specified maritime district, to use as a base for future naval operations or as a landing place for accompanying troops. The object of the defense (Blue squadron) is to prevent this, nothing being known of the enemy's plans except that the harbor chosen must be within the prescribed limits. It may be anywhere along several hundred miles of coast. Rules for the maneuvers are prepared beforehand. It is assumed that if the attacking squadron can enter a harbor, unprotected by fortifications, and remain there a length of time specified without being discovered, it has succeeded. This will allow time to land troops and prepare for defense. It is like a game of hide and seek. The commander of the Reds, being well out to sea, decides that he will try to seize one of a certain number of harbors, knowing all those that would answer his purpose. He has to find one that is unguarded and unprotected. He uses his fastest vessels as scouts. His success depends upon the rapidity and secrecy of his movements. As the Blue squadron is supposed to be much the superior in strength, the Reds are assumed to have failed in their object unless they enter the harbor selected undiscovered, or if discovered, unless the main force of the Blues is at such a distance that it cannot arrive and attack the Reds within the time allowed them to establish themselves. The problem for the Blue commander is to discover the enemy, and having discovered him, to have his forces so disposed that he can concentrate for attack a force superior to that of the Reds. He too uses his fastest vessels as scouts. Defending a friendly coast, all aid possible is given him from shore. He can establish there as many lookout stations as he pleases. Every lighthouse is a watch-tower for him. He keeps in communication with his ships and with his shore stations. If he discovers the enemy and comes within range of him with a strong force within the time fixed he wins the day. A common form of exercise in all navies is that of torpedo boats against battle-ships or cruisers. The torpedo boats go out to sea and come in at night for attack, taking advantage of every means of concealment. If seen in time they could be destroyed at once. If they can come without discovery within torpedo range, the ship attacked is supposed to be destroyed. The ships are on the lookout and try to pick them up with their search-lights. When picked up a rocket is sent up from the ship. If the torpedo boat comes within the specified distance and no rocket has been sent up from the ship, she sends up a rocket. The vessel first sending up a rocket is the victor.

Combined Army and Navy Maneuvers.— In Europe combined maneuvers of the army and navy are varied in character. In one case the scheme may comprise the embarkation of troops, their conveyance in transports under convoy of a fleet to a supposed hostile shore, the forcing of a landing under cover of the fire of the guns of the fleet, and subsequent operations on shore. Such a scheme assumes the absence of seacoast fortification at the point selected for landing. Another case may be where a powerful fleet of battle-ships, cruisers, and torpedo boats is divided into two opposing fleets to act in conjunction with corresponding Red and Blue armies on shore, the combined forces of each side working together in accordance with a common plan. This scheme may involve naval engagements between the opposing fleets, attacks upon shore batteries by ships, the manning of seacoast forts, the throwing into them of strong detachments of infantry to act as supports and to prevent a landing by the enemy, the landing of naval brigades composed of sailors and marines to reinforce troops on shore, and many other incidents.

In the United States combined army and navy maneuvers were inaugurated in 1902. The seacoast is permanently divided into artillery districts. One or more of these districts are chosen as the zone of operations. In 1902 the zone included the coast from Buzzards Bay to New London and the forts at the eastern entrance of Long Island Sound. As the ordinary garrisons are insufficient for war conditions, they are reinforced by artillery troops from stations without the zone and by militia artillery, New York and Massachusetts having regiments that have been trained in artillery work. War conditions are simulated as closely as possible. The ships to form the hostile fleet are designated. Their number and character are known to the defense. This knowledge can be assumed because particulars of the navies of all nations are published in books and are accessible to all the world; witness the accurate knowledge of the composition of the Spanish fleets in 1898. The defense knows also the date of sailing of the fleet from a supposed foreign port and the probable time of arrival in the zone of operations, but knows nothing of the enemy's plans. They may comprise attacks by day or by night and attempts to run by the forts. The fleet has, of course, charts of the waters in which the maneuvres are to take place. The location of the forts, their character, and something of their armament are known. Buoys indicating channels are supposed to be removed and lights in lighthouses extinguished. If hulks are supposed to be sunk in channels as obstructions, the naval commander is informed of them. He must count on the presence of torpedoes. An army officer as umpire and a navy officer as observer are detailed for each fort, and a navy officer as umpire and an army officer as observer for each ship. A board of arbitration to consider all questions and render decisions is composed of two army officers, two navy officers, and a fifth member selected by the other four. When ships and forts are exchanging fire with blank cartridges it is impossible to estimate results at the time. Accurate accounts

of everything done are therefore kept in forts and on ships and detailed reports are prepared for the board of arbitration. On these the board bases its decisions. In these are noted arrival within range, whether by day or by night, the time under fire, the number of shots fired from each gun, the targets selected, and so forth. Tables are prepared beforehand giving the value, in points, of the fire from each kind of gun. These are based on data obtained from previous target practice records. As ship's guns are fired from a moving platform their fire is considered less accurate than that of land guns. Night firing is less accurate than day firing. The rapidity of fire ranges, say, from six seconds between shots for the smallest rapid-fire to two minutes between shots for the 12-inch seacoast guns, the largest used. The fire of the smaller calibre guns may silence, but not destroy, unless used in conjunction with those of larger calibre. The rules for the maneuvers are formulated with a view to meet the circumstances and incidents likely to arise in an attack by a hostile fleet on the harbors of the United States. They are based on the assumption that the primary object of the maneuvers is to investigate certain systems and problems of attack and to test the training of the personnel and the efficiency of the material. Much work preliminary to the maneuvers must be done by the defense. Signal stations must be selected. All the works of the defense must be put in telegraphic or telephonic communication with each other and with the signal stations. The commander must be constantly in touch with all parts of his line. Mines must be placed in position and tested. As a ship of the navy in commission is always on a war footing, not much of this preliminary work is necessary. Let us suppose ourselves on shore and the hostile fleet sighted. The shore commander is at his post in communication with his subordinates. He selects the target and prescribes the kind of fire. The men are at the guns; the range-finding, ammunition-serving, and signal details are at their posts. The range-finder details send in the range, direction, and course of the hostile ships. Firing is begun with the heavy guns as soon as they come within range. Their object is to disable the ships. Efforts are made to fire as many shots as possible while the ships are within range. If they are running by, the time is short and every shot counts. Their fire is so accurate that a line shot can always be counted on. The elevation to be given is entirely a matter of mathematical calculation, and is given for different ranges in tables ready at hand. A shot can be dropped at any range desired, and if the range is correctly given the percentage of hits is large. When it is considered that a 12-inch shot, weighing 1,000 pounds, will, for a range of six miles, go up about half a mile in the air, the importance of correct range-finding will be appreciated. If the shot drops in the right spot a battle-ship costing millions to build and taking years to complete may be disabled. If not, the shot is wasted. History shows that land fortifications suffer but little from the fire of ships. If the ships come closer, the rapid-fire guns come into play. Their objectives would be the parts of a ship not protected by armor and the crews. The mines, which constitute one of the elements of defense, contain only dummy charges, but they are electrically connected with a shore station, and if a ship comes in contact with a mine the circuit is closed, a fuse on shore is blown, and the ship is considered out of action. At night the search-lights are kept constantly at work to detect ships if they approach and to throw beams of light upon them so as to make clearer targets. All the incidents of the day on the ships and in the forts are summed up in the reports, and on these reports are based the decisions of the board. Throughout the maneuvers the fleet endeavors to accomplish its object, seeking out weak points in the defense and undefended lines of approach, or trying to run past in a fog or under cover of darkness. As the forts are stationary, they must wait until the enemy comes within range. Night and day the utmost vigilance must be exercised. If the scheme for the maneuvers should give a torpedo boat flotilla as an adjunct for the defense or if it should contemplate the landing of troops from transports convoyed by the fleet, to seize a position on shore at a place not protected by forts, necessitating on the part of the defense an additional infantry supporting force to oppose landing parties, the plans of the respective commanders would be modified accordingly. The decision as to whether the fleet or the land forces win is of minor importance. The maneuvers are of great value to both the army and navy. For the former they give instruction in the most efficient means of coast defense, including the co-ordination of all its various elements; the best system of fire control; the best location and employment of search-lights and range-finders; the best means of obtaining and transmitting information. They serve to point out any defects in the location and plans of the fortifications, and whether the number, type, and mounting of guns are the best adapted for the purpose at any particular site. For the navy they afford a test of the means of obtaining the ranges of the forts and batteries, and of conveying the information to the officers in charge of the guns. They give information as to the effect of mines and obstructions in impeding the movements of ships and the methods to be used in forcing such a passage or in removing the obstructions. They give instruction as to the best manner of approach and of maneuvering under fire, the formations to be used, the speed, and the distance between ships; the method of attacking by night or in a fog; the use of the search-light for lighting the target or blinding the eyes of the enemy's gunners or range-finders. The maneuvers rouse the interest and stimulate the *esprit de corps* of the personnel of both services and teach it to make the best use of the material placed in their hands under conditions as nearly as possible like those of actual war.

Col. W. A. Simpson,
Asst. Adjt.-Gen. U. S. Army.

Army Transport Service. At the outbreak of the war with Spain the water transportation in the possession of the United States consisted of a few small tugs, ferry-boats, and launches. Suddenly confronted with the necessity of despatching armies across the seas, it is not surprising that some confusion and delay

were encountered in selecting, chartering, and assembling fleets capable of transporting troops, with their guns, animals, and impedimenta, to Cuba, Porto Rico, and the Philippine Islands. To convert the vessels composing the several fleets from ordinary freight-ships into commodious and comfortable troop-transports required time and much outlay. The arrangement of sleeping accommodations for the men, stalls for the animals, increased water-supply, and ventilation involved a practical reconstruction of the interior of every vessel. It was particularly necessary to have those vessels destined for the Philippines made safe and comfortable, for it was anticipated that the troops might pass direct from the decks to the battle-field. Hospital ships were fitted out as quickly as possible, and served a useful purpose during the time of greatest need.

It was apparent at the outset that the problem of water transportation required careful and continuous study, and immediately after the surrender of Santiago de Cuba a division of transportation was created by the secretary of war and charged with supervision and control of all rail and water transportation; with the inspection of ships with reference to charter or purchase for use as transports, and with the arrangements for sending troops by rail to and from the various ports. When it became apparent that vessels would be required for a prolonged period, and that it was a very expensive proceeding to alter chartered vessels, the department began to purchase such ships as seemed best adapted to use as transports. Aside from the mere act of affording a passage to troops across the seas, the question of furnishing them supplies after landing involved many intricate problems, each requiring a special solution. American troops submit cheerfully to any amount of necessary hardship, but consider themselves entitled to the best of everything, regardless of cost, when the emergency has passed. For supplying their needs, it was necessary to construct refrigerator compartments in the transports to carry fresh beef and other perishable stores to the most remote and hitherto little known islands of our new possessions.

During the first few months of the heavy demands for transportation, the quartermaster's department was much hampered because vessels of foreign register could not be employed for the service, and Congress refused to grant American register to such vessels. Nevertheless, by 1 July 1898, 43 chartered vessels had been secured and fitted up for the transportation of troops, animals, and supplies. The difficulties and expense attendant upon securing efficient service with chartered vessels led to the gradual substitution of transports purchased by the government and permanently fitted up as troopships. The largest and best transports averaged nearly 6,000 tons capacity; and when, after some practical experience, a general plan of fitting up had been adopted, the transport service became a prominent feature of army administration, and attracted the attention and admiration of the civilized world. The urgency of the situation on the Pacific compelled a continuance of the charter system; but a fleet of government transports was gradually put in commission on the Atlantic, and as soon as the withdrawal of the volunteer army from Cuba permitted, many of the transports were sent to Manila by way of the Suez Canal and put on the San Francisco-Manila route. The Grant, Sherman, and Sheridan were the first vessels fitted out for this service, and their sailing from New York for Manila marked a new era in the occupation of the Philippines. The character of these transports may be comprehended by the statement that the Grant sailed from New York on 19 Jan. 1899, with the Fourth U. S. infantry and one battalion of the Seventeenth U. S. infantry, with a total strength of 50 officers and 1,703 enlisted men. The Sherman sailed on 2 February with the Third U. S. infantry and one battalion of the Seventeenth U. S. infantry, with a passenger list of 1,812 persons, followed by the Sheridan on 19 February with the Twelfth U. S. infantry and the Third battalion, Seventeenth infantry, with a total passenger list of 2,017 persons. These vessels made the long voyage to Manila with such success and comfort that the regiments were enabled to enter immediately upon active service. The experience of these voyages dictated some valuable suggestions, which were availed of at once in making desirable changes to perfect the transport service generally.

The large number of troops remaining in Cuba and Porto Rico after the return of the main body of regulars and volunteers necessitated the establishment of a regular line with weekly sailing dates. Advantage was taken of the regular steamship lines as far as possible for the larger movement of returning troops. The transportation to Spain of the Spanish prisoners was accomplished under contract, in accordance with stipulations under which the surrender of Santiago took place. More than 22,000 Spanish prisoners were thus returned from the eastern end of Cuba to Spain within 60 days of their surrender, in an economical and apparently satisfactory manner.

The outbreak of the insurrection in the Philippines made it necessary to hasten relief to the volunteer regiments still held in those islands, and the presence there of the old Spanish garrisons which, under the terms of the treaty of peace, were entitled to repatriation, made it desirable that they should be returned to Spain without delay. The transport service was strained to the utmost limit, but fulfilled its part in the most gratifying manner. During its first year of existence a total of 202,587 passengers were transported across the seas by army transports without responsibility for the loss of a single life.

The question of transportation of animals was one requiring much study and experiment, for there was little experience available to guide the department in a solution of the problem of landing cavalry horses in fit condition for service after a voyage of 7,000 miles. Some discouraging losses of mules occurred at a critical moment in the campaign against the insurgents, but gradually the system was perfected and the loss of animals actually reduced below the percentage of loss from injury and disease which should be expected in the herds on shore. Nearly 20,000 animals were transported during the year ending 30 June 1901.

At a time when every effort was being put forth to meet the requirements of the military situation Porto Rico was devastated by a hurricane, and the transport service was called upon to distribute relief stores to the unfortunate in-

habitants who, just released from the worries of war, found themselves threatened with famine and pestilence.

As conditions in the Philippines gradually settled down to a guerrilla warfare, the troops were distributed at about 400 stations, necessitating an inter-island transport service. Just as everything was becoming adjusted to the new conditions which followed the dispersal of Aguinaldo's army, the unfortunate "Boxer" outbreak took place in China. The experience already obtained enabled the department to handle the transportation question in such a way as to win the admiration of all the foreign contingent composing the Chinese relief expedition which finally entered the sacred city of Pekin.

As the insurrection gradually died away, and the volunteers who enlisted for Philippine service in 1899 were brought back to the United States, the number of transports was reduced by disposing of the least efficient in respect of economy as well as of carrying capacity. The vessels remaining in service represent the finest types of transports ever in the service of any nation. They contain all the improvement that several years of wide experience seemed to justify. The record of the army transport service reflects credit upon the War Department. The remarkable freedom from accidents and loss of life indicates a high degree of efficiency and discipline in the officers and crews of the transport fleet. The records show that considerably more than 500,000 passengers have safely crossed the seas in the army transports. The movement of such a vast number of people, many of them over the sea from 7,000 to 11,000 miles, without the loss of a passenger chargeable to the transport service, is a record which compares most favorably with those of all the great commercial lines which, through long experience, have reduced the transatlantic passenger traffic to an exact science.

The army transport service has withdrawn its fleet from the Atlantic, and has materially reduced the number of vessels in commission on the Pacific. The success of the service having become widely known, at the session of 1902–3, an act was passed providing that it should not be abandoned without the consent of Congress. The experience of these recent years justifies the belief that, if our government shall be again confronted with the direful necessity of organizing and transporting armies across the seas, there will be no repetition of the scenes and incidents which characterized the early days of the war with Spain. If these expectations materialize, the great expense and labor incident to putting in commission the magnificent fleet of ships under the army transport service will not have been in vain.

William H. Carter,
Brigadier-General General Staff.

Army War College, a department of the United States military educational establishment, authorized by Congress in 1900. Brig.-Gen. William Ludlow was made chief of the board which drafted the regulations. Its general purpose is the unification of the systems of instruction at the four existing service institutions; the development of these systems; and the most advanced professional study of military problems. The officers of the college exercise a general supervision over the course of study in each of the present service schools. This supervision extends to all civil institutions to which the government details an officer for military instruction. The faculty of the college study the military organization of the United States with an eye to a complete understanding of its practical efficiency of operations, and constitute an advisory board to which the secretary of war can turn at any time for details and recommendations as to any point in the mechanism of the whole military service. The study of plans of campaigns by the college and the accumulation of military information make the inauguration of a campaign, in case of war, only a matter of the issuing of the necessary orders by the secretary, as all the requirements will have been carefully studied out beforehand.

Army-worm, the caterpillar of the moth *Leucania unipunctata.* The adult measures about one and a half inches across the expanded wings, which are dull brown, the anterior pair bearing near the centre a small white dot which has suggested the specific name. Like most moths, this species flies at night and in seasons when they are specially abundant, are the most commonly captured insects at lights and baits of sugar or syrup, of which they are very fond. The eggs are usually concealed on herbage in fields, especially where vegetation is luxuriant, as in wheat fields. Unless checked by enemies the caterpillars quickly reach maturity, pupate a short time under ground, emerge, pair, and lay eggs from which a larger brood than the first is hatched. This brood, after devouring every green thing soft enough to eat, spread destruction as they march, army-like, from the place where they were hatched to fresh feeding grounds. When full grown these larvæ pupate; some for only a short time, others until the following spring. The former lay eggs for a third brood of caterpillars which endeavor to pass the winter as larvæ, so that larvæ, pupæ, and adults may be found throughout the year. The caterpillars attain a length of about two inches, are dark gray, striped with light yellow and green. Though annually common east of the Rocky Mountains they are generally so well controlled naturally that their depredations are insignificant, and usually when they do become a pest their enemies so quickly master them that they very rarely are troublesome in the same locality two years in succession. The most important of these enemies are fungous diseases and, especially, parasitic insects. Artificial controls are almost all mechanical. Occasionally the larvæ of the first brood may be noticed in time to apply an insecticide (q.v.) such as Paris green mixed with soap-suds instead of water to make it more adhesive to the grass; but usually the safest plan is promptly to bury the crop by plowing, or to burn it. If migration has started, a strip of land should be plowed across the line of march, harrowed, and rolled constantly to crush the worms, or kerosene emulsion, diluted only five times, must be sprayed upon the advancing worms and also upon their recent feeding ground. The name army-worm is given to other species of caterpillars, especially to *Laphygna frugiperda,* which is better known as grass-worm. Consult 'Third Report' United States Entomological Commission (Washington 1883); 'Bulletin 133' Cornell Experiment Station.

Arna, or **Arnee**, är'nē, a large animal of the ox genus, a native of India and the Indian Archipelago. See Buffalo.

Arnauld, är-nō', an ancient noble family, among whose most distinguished members are the family of Auvergne. (1) Angelique: b. Paris 24 Nov. 1624; d. 24 Jan. 1684. She was the granddaughter of the great Arnauld and was abbess of the famous nunnery of Port Royal from 1678. See Lives by Martin (1876); Monlaur (1901). (2) Antoine: b. Paris 1560; d. 1619. He was a zealous defender of the cause of Henry IV., and was distinguished for several political pamphlets, and for his powerful and successful defense of the University of Paris against the Jesuits in 1594. He drew on himself the hatred of the Jesuits, but was esteemed the greatest lawyer of his time. His numerous children formed the nucleus of the sect of the Jansenists (see Jansenius) in France. (3) Antoine, called the "Great Arnauld," youngest child of the lawer Antoine Arnauld: b. Paris 6 Feb. 1612; d. Brussels 9 Aug. 1694. He devoted himself to theology, and was received in 1641 among the doctors of the Sorbonne. In the same year he attacked the Jesuits in two works, 'De la fréquente Communion' and 'La Théologie Morale des Jésuites,' the first of which occasioned much controversy, because it applied the principles of the Jansenists to the receiving of the sacrament. After 1650, when Jansenism had become an object of public odium and the watchword of an important party in the state, Arnauld engaged in all the quarrels of the French Jansenists with the Jesuits, the clergy, and the government, was their chief writer, and was considered their head. The intrigues of the court occasioned his exclusion from the Sorbonne (1656), and the persecutions which compelled him to conceal himself. After the reconciliation between Pope Clement IX. and the Jansenists, in 1668, he appeared in public, and enjoyed the homage which even the court did not refuse to his merits and talents. He now attacked the Calvinists in many controversial tracts ('Renversement de la Morale de Jesus Christ par les Calvinistes'; 'L'impiété de la Morale des Calvinistes,' etc., and with his friend Nicole composed the great work, 'La Perpetuité de la Foi de l'Eglise Catholique touchant l'Eucharistе,' in opposition to them. On account of the new persecutions of the court, or rather of the Jesuits, he fled, in 1679, to the Netherlands. He was a man of a vigorous and consistent mind, full of solid knowledge and great thoughts; in his writings, bold and violent to bitterness, undaunted in danger, and of irreproachable morals. His works were published at Lausanne between 1775 and 1783, and again at Paris in 1843. (4) Jacqueline Marie, sister of the preceding, a French nun better known as Marie Angélique de Sainte Madeleine. She was famed for piety and was prominent among the Jansenists. She was prioress of Port Royal. See Life by Martin (1873).

Arnauts, är'nâts, or **Albanians**, a people of mixed origin, who have spread in the western part of European Turkey, along the coasts of the Adriatic and Ionian Seas. They call themselves *Skipetars*, that is, inhabitants of the mountains; by the Turks they are called *Arnauts.*. Their language is regarded as a descendant of the ancient Illyrian language, and contains a considerable admixture of Greek, Roman, German, Slavonic, and Turkish words. The Arnauts in the coast towns generally speak Greek as well as their own language. They are divided into several tribes, among whom the Suliotes in the south are partly of Greek origin. As regards religion they are divided between Christianity and Mohammedanism. They are frank toward friends and superiors, but indulge in every kind of artifice and perfidy toward their enemies. The Tosks of southern Albania have in some respects not so good a reputation as the Gheggas of the north, but, owing to their contact with Greece, they are further advanced in civilization. War is the favorite occupation of the Arnauts. For arts and trades they have no inclination. Agriculture they esteem not so honorable an occupation as arms. They form the finest body of troops in the Turkish army.

Arn'hem, or **Arnheim**, a town in Holland, in the province of Gelderland, on the right bank of the Rhine. It was once fortified, but the fortifications have been converted into public walks. The environs of Arnhem being more agreeable than those of almost any other town in Holland, it is much frequented by summer visitors. Among the chief buildings may be mentioned the Groote Kerk, or high church, containing the fine monument of Charles, Duke of Egmont; the Prinzenhof, the town-house, and the barracks. Its manufactures consist of cabinet wares, mirrors, carriages, mathematical and physical instruments, etc., and there are numerous paper-mills in the neighborhood. Its trade, partly direct in grain, and partly transit to Amsterdam, Rotterdam, etc., is important. In 1795 it was stormed by the French, who were driven from it in 1813. Pop. (1900) 56,812.

Ar'no (anciently *Arnus*), one of the largest rivers of Italy. It divides Tuscany into two parts, and rises in the Apennines, on the east of Florence, on the border of Romagna, 15 miles west of the sources of the Tiber. It then turns southward toward Arezzo, after which it runs westward through Florence, and enters the Mediterranean four miles below Pisa. From any hill in the neighborhood of Florence the view into the valley of the Arno is charming. The entire course of the river is about 140 miles.

Arnold, Abraham Kerns, an American soldier: b. Bedford, Pa., 24 March 1837. He was educated at West Point, and commissioned 1st lieutenant, Fifth Cavalry, 17 July 1862. He was brevetted captain for gallant and meritorious service in the battle of Gaines' Mill, Va., and major for similar service at the battle of Todd's Tavern, Va. He received a Congressional medal of honor for gallantry in action at Davenport Bridge, Va., 18 May 1864. He commanded the field operations in southeastern Arizona against the Apaches in 1879, and against the Crows in 1887. During the Spanish-American war he commanded the 2d Division of the 7th Army Corps in Cuba. He has written 'Notes on Horses for Cavalry Service' (1869).

Ar'nold, SIR **Arthur,** an English statesman and author: b. 1833; d. 1902. He acted as assistant commissioner to administer the Public Works Acts during the cotton famine, 1863–6, and afterward wrote 'The History of the Cotton Famine.' Other literary productions have been: 'From the Levant' (1868); 'Through Persia by Caravan'; 'Social Politics'; and 'Free Land.' He sat in Parliament as a Liberal member for Salford, 1880–5. Established and was president of the Free Land League from 1885 to 1895; was chairman London County Council, 1895 and 1896, and was knighted in June 1895. He was a brother of Sir Edwin Arnold (q.v.).

Arnold, Benedict, a colonial governor of Rhode Island: b. England, 21 Dec. 1615; d. 20 June 1678. He was a leader of the opposition to Samuel Gorton's settlement at Pawtuxet, 1641. His knowledge of Indian languages enabled him to effect important negotiations with the Indians in 1645. In May 1657 Arnold succeeded Roger Williams as president of the colony, and upon the granting of the royal charter to the colony in 1663, was made the first governor, being re-elected in 1664, 1669, 1677, 1678. He took an active part in the reconciliation and union of the two colonies of Rhode Island and the Providence plantations. The famous windmill at Newport, whose erection was long ascribed to the Northmen, appears to have been built by him.

Arnold, Benedict, an American general, commonly known as "The Traitor": b. Norwich, Conn., 14 Jan. 1741; d. London, Eng., 14 June 1801. He descended from a leading Rhode Island family; was fairly educated. He was early noted for athletic prowess, reckless daring, and resource, and as a man displayed a proud, passionate, uncontrolled nature, quickly responding to affection or resentment. He became a druggist and bookseller in New Haven at 21; prospered, and embarked in the West India trade. At the news of the battle of Lexington, he armed a body of 60 volunteers, marched to Cambridge, and proposed the capture of Ticonderoga and Crown Point. The Massachusetts Provincial Congress gave him supplies therefor, a commission as colonel, and authority to raise troops; but finding at his recruiting ground that an expedition had already started, he hastened after it and claimed command under his commission. As the commander was Ethan Allen, both Allen and the troops declined to pay any attention to it; and Arnold under protest accompanied it as a volunteer, and entered Ticonderoga beside Allen. Four days later he was joined by a band of his own, and at once sailed down Lake Champlain and captured St. John's.

Refused the command of the captured forts, he returned to Cambridge, proposed to Washington an expedition against Quebec, and on 11 September left for the Kennebec with 1,100 men, to cross the divide between its headwaters and the early Chaudière. After a fearful march through sleet storms, frozen lakes, rapids, and forests, he reached Quebec 13 November, scaled the heights to the Plains of Abraham, and dared the garrison of thrice his numbers to come out and fight. They refused, and reinforcements from Sir Guy Carleton compelled him to fall back. On the arrival of Montgomery the two undertook an assault (31 December) in which the latter was killed and Arnold's leg shattered, but he still blockaded the place till relieved by Wooster in April. Meantime he had been commissioned brigadier-general and given command of Montreal. On the expulsion of the United States troops from Canada, the British planned an invasion by way of Lake Champlain, and Arnold went to Ticonderoga and spent the summer building a fleet to bar their way. On 11 October he fought one of the most obstinate and heroic naval battles in our history, near Valcour Island off Plattsburg. Hopelessly outnumbered, he nevertheless escaped with the most of his boats and all of his men. The British retired to Montreal, and the Americans sent Washington the 3,000 men which enabled the battles of Trenton and Princeton to be fought.

One of Allen's men, whose promotion had been opposed by Arnold on the ground that he had plundered officers' baggage in Canada, brought counter-charges of malfeasance against him in December, which the board of war pronounced "cruel and groundless." But Congress in making five new major-generals, 19 Feb. 1777, passed over Arnold, the senior brigadier, on the ground that Connecticut had two already, and appointed Stirling, Mifflin, St. Clair, Stephen, and Lincoln, all of whom together had not a tithe of Arnold's abilities or achievements. He had a right to be enraged: but he contented himself with asking to be made ranking officer as before; offered to serve under his juniors for the present; and in Tryon's invasion of Connecticut in April, did such splendid deeds that Congress for very shame gave him the major-generalship, but still left him at the foot. Meantime he was in pressing need of having his claims against Congress settled. Pay and supplies were hard to extract from that body, and Arnold, in his Canadian expedition and elsewhere, had used his own money freely and pledged his credit repeatedly to keep the movements from utter collapse for lack of them. But the claims were large, Congress was suspicious and dilatory, Arnold's business was half ruined, and he needed the money. He was at Philadelphia, seeking restoration of his rank, and, his patience exhausted at the refusal of Congress to act in his behalf, had asked permission to resign, when Burgoyne's invasion of 1777 loomed up imminent, and Washington wrote urgent and repeated requests to Congress to send Arnold north to oppose him. Soothed by this flattering request, he withdrew his resignation and hastened north. In this crisis, it is to him that the country owed its salvation. By a decoy messenger he scattered St. Leger's army in a panic, its Indian allies turning against it and butchering the whites as they retreated. He then foiled Burgoyne's flanking attempt at Freeman's farm 19 September, unsupported by Gates, and in the final battle of 7 October, took command without official right, and routed Burgoyne's army. This victory gained for the United States the French alliance, and ultimately the surrender at Yorktown. During the engagement Arnold's leg was shattered and he remained in Albany disabled till spring. On 20 Jan. 1778, Congress restored him his senior rank.

In June he was given command of Philadelphia, where he became engaged to a beautiful girl of a loyalist family, Margaret Shippen. The testimony is conclusive that she had nothing to do with his fall; but her family and the always powerful loyalist society of Philadelphia had for the next two years a great influence over him. The prospects of the United States grew so bad that even Washington wellnigh lost all hope; the English government offered such seductive proposals that many patriotic citizens considered it wanton wickedness to prolong bloodshed and misery, when all that the war was waged to obtain was offered with fair guarantees. Congress was so faction-ridden and incompetent that many more thought the future of independence most calamitous even if it could be obtained; the soldiers were unpaid and unclothed, deserting fast, and nearing a dangerous mutiny which soon broke out. In this state of things, every influential officer at odds with Congress was besieged with expressions of loyalist opinion, and Arnold was in the thick of all that could shake his resolution. As always, he lived beyond his means, and as always he was in bitter feud with the other powers. He had determined to retire and settle on a New York land grant, when he was assailed with a series of charges by the State authorities, headed by Joseph Reed, president of the executive council. Most of the charges were frivolous, but two,— that he courted the loyalists at the expense of the patriots, and that he had used his position to make illegal purchases,— were serious. A committee of Congress acquitted him absolutely except on two foolish counts, and advised ignoring them. Arnold was satisfied and resigned his command. Reed protested on the ground that he had more evidence, a fresh committee referred the charges to a court-martial, and Arnold spent month after month urging a speedy trial. Reed with equal pertinacity delayed his "evidence" till more than a year after the first indictment; the court-martial returned its verdict 26 Jan. 1780. The court returned the same verdict as the committee, but recommended that Arnold be reprimanded for two frivolous counts, and Washington was compelled to discharge this odious office. He did it in the mildest of terms, however, and offered Arnold the post of honor in the next campaign.

But it was too late: the public disgrace imposed on Arnold after his magnificent services, wounds, and losses filled him with determination for revenge, justified to himself by the reasons above stated. Inviting examples were put before him: chiefly of Monk, who had restored Charles II. and been rewarded by honors and gratitude; more pertinently, of Marlborough's betrayal of James II. by taking his whole army over to William; and others. He really seems to have argued himself into believing that he should be playing the part of a patriot by ending the war at a blow, restoring peace and prosperity, giving the colonies a much better government than they had now or before the war, and practically secure independence under the English offers; and that this once done, all parties would thank and honor him, as he could control negotiations with the English government. This decisive blow would be the putting of the English in control of the Hudson, gaining at a stroke the object of Burgoyne's and other campaigns,— severing the New England colonies from the rest, and giving the enemy New York, the central colony. For this end he asked of Washington the command of West Point, the key of the Hudson, with its mass of military stores: the colonies could hardly hold out after such a loss, aside from the strategic gain. He pleaded ill health for asking this instead of the proffered command; and Washington accorded it to him. After the capture of André he escaped to the Vulture, and issued a proclamation justifying himself and asking his countrymen to do likewise, making glowing offers to deserters. The British made him a brigadier-general, and on 20 December he sailed for the James River, where he burned Richmond, intrenched himself for the winter at Portsmouth, and in June 1781, returned to New York. In September he was ordered to raid New London, Conn., 14 miles from his birthplace. He burnt a quantity of shipping and stores, which set fire to and partially destroyed the town; and the "massacre" of Fort Griswold was achieved by a detachment on the other side of the river Thames.

Shortly after the surrender of Cornwallis in October, he was sent to London to confer with the ministry on the further conduct of the war. The king and the court received him well; but the Liberals denounced him as bitterly as the Americans, and a large share even of the Tories distrusted a renegade and detested a betrayer of his trust. The officers in the British army despised a colonial as heartily as in Braddock's days, and therefore it was found impossible to give him the employment in the army he eagerly coveted. In 1787 he removed to New Brunswick and engaged in the West India trade, with two sons; but in 1791 he returned to London. The next year he fought a bloodless duel with the Earl of Lauderdale, for a stinging insult of the latter in debate in the House of Lords. In 1794 he went to the West Indies to settle, but the Anglo-French wars made it impossible, and he was twice extricated from great personal danger by his alert resource. He rendered great service to the British commanders and in 1795 was thanked by the committee of West India planters, with the wish that he might remain in public service. He also formulated plans for the British capture of the Spanish West Indies; and in 1798 asked for military service, but his request was not granted, even after personal solicitation. The refusal helped greatly to break him down; his unthrifty habits had drained his purse, and he had intense pecuniary embarrassments. He was active in fitting out privateers, a speculation which gave him more anxiety than profit; and he died at 60, a worn-out, harassed, unhappy man, seeing that his crime was also a colossal blunder. But that he had first saved the country he tried to ruin, that he was grossly wronged and greatly tempted on his best as well as on his worst side, and that he deserves far more pity than hate, cannot be doubted. See 'Lives' by Sparks (1838); I. N. Arnold (1880); **Todd (1903).**

Ar'nold, Sir Edwin, English poet and journalist: b. Gravesend, 10 June 1832; d. 24 March 1904. He graduated from Oxford in 1854; taught for a while in Birmingham; and became principal of the Sanskrit College at Poona, near Bombay, where he rendered important ser-

vice to the government during the great rebellion in India. Returning to London in 1861, he joined the editorial staff of the *Daily Telegraph.* He has twice visited the United States on lecture tours. Of his original poetry, inspired by Oriental themes and legends, the most famous work is 'The Light of Asia, a Poetic Presentation of the Life and Teaching of Gautama' (1876); 'Indian Idylls' (1883); 'Pearls of the Faith'; 'Sa'di in the Garden'; 'The Light of the World'; 'Potiphar's Wife and Other Poems'; 'India Revisited'; 'Japonica'; and 'The Tenth Muse and Other Poems'; 'East and West' (1896); 'The Voyage of Ithobal' (1901), are among his many works. The popularity gained by 'The Light of Asia' has not been sustained by the appearance of his later work.

Ar'nold, Edwin Lester, an English author, son of Sir Edwin Arnold. He has written 'A Summer Holiday in Scandinavia' (1877); 'On the Indian Hills, or Coffee Planting in Southern India' (1881); 'Bird Life in England' (1887); 'England as She Seems' (1888); the novels 'Phra, the Phœnician' (1890), and 'The Story of Ulla' (1895).

Ar'nold, George, an American poet: b. New York city, 24 June 1834; d. New Jersey, 3 Nov. 1865. Adopting literature as a profession he contributed prose and verse to 'Vanity Fair,' 'The Leader,' and other periodicals of his day. The "Macarone" papers established his reputation as a humorist, and the 'Jolly Old Pedagogue' is his best known poem. During the Civil War he did military duty at one of the forts on Staten Island. His published volumes are: 'Drift: a Seashore Idyl' (1866); 'Poems, Grave and Gay' (1867); 'Poems'; ed. with a Biographical Sketch by Wm. Winter (1870).

Arnold, är'nōlt, **Hans,** the pseudonym of Bertha von Bulow. See BULOW, BERTHA VON.

Arnold, Isaac Newton, an American lawyer and author: b. Hartwick, Otsego County, N. Y., 30 Nov. 1815; d. Chicago, 24 April 1884. Admitted to the bar in 1835, he removed in 1836 to Chicago, where he resided the remainder of his life, engaged in legal practice and taking an active part in politics. From 1861 to 1865 he was a member of Congress, and had a prominent share in measures leading to the abolition of slavery. His ablest speech was on the confiscation bill, 2 May 1862. Upon his retirement from Congress President Johnson appointed him an auditor of the United States treasury. A lifelong friend and intimate of Lincoln, he wrote 'History of Abraham Lincoln and the Overthrow of Slavery' (1867; new ed. 1885). His 'Life of Benedict Arnold; His Patriotism and His Treason' (1879), is in the nature of an apologia. 'Recollections of the Early Chicago and Illinois Bar' appeared in 1880.

Arnold, är'nōlt, **Johann Georg Daniel,** an Alsatian dialect poet and jurist: b. Strassburg, 18 Feb. 1780; d. there, 18 Feb. 1829. His lyrics (in High German) are meritorious, but he is at his best in 'Pentecost Monday' (1816), a comedy in Strassburg dialect and rhymed Alexandrine verse, pronounced by Goethe "an incomparable monument of ancient Strassburg custom and language, a work which in clearness and completeness of intuition and ingenious delineation of detail can scarcely be equaled." He was a professor in the College of Strassburg and wrote a notable legal work entitled 'Elementa Juris Civilis Justinianei cum Codice Napoleoneo et Religuis Legum Codicibus Collata' (1812).

Arnold, är'nold, **Lewis G.,** an American soldier: b. New Jersey, 1815; d. 1871. Educated at West Point he served as second lieutenant in the second Seminole war (1837-8) and was in active service during the war with Mexico. He distinguished himself in the Federal army during the Civil War, retiring from the service with the rank of lieutenant-colonel of regulars in 1864.

Ar'nold, Matthew, an English poet and critic: b. Laleham, 24 Dec. 1822; d. Liverpool, 15 April 1888. A son of Dr. Thomas Arnold, the historian of Rome and famous head-master of Rugby, he was educated at Winchester, Rugby, and Balliol College, Oxford, where he gained the Newdigate prize for his poem 'Cromwell' (1843), and in 1845 was elected Fellow of Oriel College. For a short time he taught the classics at Rugby, then became private secretary to the Marquis of Lansdowne, 1847-51, who appointed him an inspector of schools, a post he held until 1883, when Gladstone conferred on him a civil list pension of £250, which enabled him to retire. While the routine and details connected with this work were ever distasteful to him, he performed them thoroughly and conscientiously, and his suggestions were not without influence on English secondary education. Three times he visited the Continent, commissioned officially to study school discipline and educational methods there, and his results were summed up in the three books: 'Popular Education in France' (1861); 'A French Eton' (1864), and 'Schools and Universities on the Continent' (1868). His official reports from 1852-82 were published by Sir F. Sandford and are of considerable educational interest and value. From 1857 to 1867 he delivered the lectures connected with the Professorship of Poetry at Oxford. In 1883-4 and in 1886 he visited the United States, lecturing in the principal cities. In 1873 he took up his residence at Cobham where he remained till his death, which occurred suddenly from heart disease. In general his domestic life was most happy, but sadly clouded by the successive deaths of three promising sons.

It is as poet and critic that Arnold was best known in his own day and his poetry and criticism give him his distinguished position in English literature, a position which is bound to be regarded more highly by posterity than it was by his contemporaries. His poetry is more classical in form and atmosphere than that of any other English poet except Milton. But he is classical in a general sense only — not imitative nor affected. His classicism lies in his serenity and urbanity of mind and temperament; in his lucidity, in his Virgilian grace and dignity. In thought and suggestion he was frankly contemporary. If his poetry has a predominant note, it is that of pathos. 'Balder Dead' is a masterpiece of noble sadness and dignified narrative. 'Sohrab and Rustum,' with its perfect unity of action, ends in a situation of matchless pathos. Portions of 'Tristram and Iseult' are among the finest examples of descriptive poetry, and 'Thyrsis' is one of the most beautiful elegiac poems in the language. Some of his lyrics, too, are exquisite, for example, 'A Summer Night,' 'The Youth of Nature,' 'The Youth of

Man,' 'Isolation,' 'Faded Leaves,' and 'A Southern Night.' The 'Forsaken Merman' has passages of delightful fancy, and 'The Church of Bron' displays imagination of a high order. The great merit of his verse is its uniform level of fine thought, expressed with notable grace, clearness, and restraint.

As a critic Arnold has no superior and is without a rival in English literature. He made far less errors than Johnson, was better informed than Dryden, was broader and more judicial than Pope. His judgments upon our poets have become generally accepted and are rarely questioned. His view of what criticism should be is given in the well-known essay on 'The Function of Criticism at the Present Time'; in his own work and practice he seems to have conceived its duty to be "to lay down decisive canons of cultured judgment, to sift the sound from the vicious, to maintain the purity of language and of style." He greatly modified the accepted form of the English critical essay and brought it more into line with the French *causerie* as developed by Sainte-Beuve, whose influence on Arnold was considerable. His characterizations of Spinoza, Marcus Aurelius, and Heine are masterly, and his appreciations of Wordsworth, Byron, and Goethe are without equals. The essays 'On Translating Homer' are now classics. Homer's characteristics are nowhere else set forth with such understanding, sympathy, and authority, or the rules of translation so unanswerably deduced from them. His social, theological, and political criticism forms a distinct part of his work. He was thoroughly discontented with English indifference to ideas in literature, politics, and religion, and the absorption of his countrymen in material pursuits. He made it his duty to arouse them from their intellectual apathy, and urge their attention to the higher things of life and the spirit. As a consequence he was greatly misunderstood and received much unmerited criticism and contempt. But his ideas had a marked influence on his generation, and many of them have triumphantly prevailed. The books in which he carried on his crusade against British "Philistinism" were: 'Culture and Anarchy' (1869); 'Saint Paul and Protestantism' (1870); 'Friendship's Garland' (1871); 'Literature and Dogma' (1873); 'God and the Bible' (1875); 'Last Essays on Church and Religion' (1877). He repeatedly evinced a happy faculty for doing the right thing at the right moment. The storms of controversy and attack which his telling and keen criticism of manners caused, never ruffled him, or led him to retort in kind. His phrases became current coin, his cutting "labels" stuck to the things he satirized and have passed into permanent use. This gift of sending forth phrases to ring through and be accepted by a whole generation is a rare power. Forever associated with him in the sense in which he used them are the now proverbial expressions, "Philistinism," "the great style," "the young lions of the press," "the Zeit Geist," "the note of provinciality," "sweet reasonableness," "sweetness and light," "the stream of tendency, not ourselves that makes for righteousness." It was his expressed wish that he should not form the subject of a biography. In 1895 his letters from 1848 to 1888 were gathered and edited in two volumes by G. W. E. Russell. These were written almost entirely to members of his family and close friends, and show him in the happiest light.

Bibliography.—A bibliography of Arnold's writings was published by Thos. B. Smart in 1893. His poetical works appeared as follows: 'The Strayed Reveller, and Other Poems' (1849); 'Empedocles on Etna' (1852); 'Poems' (1853; 3d ed. 1857); 'Poems,' second series (1855); 'New Poems' (1867); and a complete edition in three volumes 1885. His critical works, beside those mentioned above, were: 'On Translating Homer' (1861-2); 'Celtic Literature' (1867); 'Essays in Criticism,' first series (1865); 'Mixed Essays' (1879); Irish Essays' (1882); 'Discourses in America' (1885); 'Essays in Criticism,' second series (1888). Contemporary literature is filled with criticism of the various aspects of Arnold's work. A few of the more important studies are: Fitch, 'Thomas and M. Arnold' (1897); Robertson, 'Modern Humanists' (1891); F. Harrison, 'Tennyson, Ruskin, and Mill, and Other Literary Estimates' (1900), an excellent appreciation; Brownell, 'Victorian Prose Masters' (1902); Walker, 'The Greater Victorian Poets' (1895); A. Galton, 'Two Essays Upon Matthew Arnold' (1897). Prof. Saintsbury's volume on Arnold is too hostile and unsympathetic to be of any critical value; and Mr. Herbert Paul's book in 'The New Englishmen of Letters' series is hopelessly futile and inadequate.

Ar'nold, Richard, an American soldier: b. Providence, R. I., 1828; d. 1882. He was graduated from West Point and served with distinction in the Federal army during the Civil War, being brevetted major-general of volunteers in 1865.

Ar'nold, Samuel, an English composer: b. London, 1740; d. 1802. In 1760 he was appointed a composer at the Covent Garden Theatre, and set to music the 'Maid of the Mill.' He also produced the oratorios of the 'Prodigal Son,' the 'Resurrection,' and others. He was made a doctor of music in 1773, and in 1783 was appointed organist of the chapel royal. He edited the works of Handel, in 36 volumes folio. In 1794 he was made organist at Westminster Abbey. In 1708 he composed his oratorio of 'Elijah.' Various as were his compositions, his inventive talent was but limited. His 'Cathedral Music' was published in 1790.

Ar'nold, Samuel Greene, an American historian: b. Providence, R. I., 12 April 1821; d. there, 12 Feb. 1880. He was graduated from Brown University in 1841, and traveled extensively in Europe, South America, and the East. He was lieutenant-governor of Rhode Island 1852, 1861-2, and sat for part of a term in the United States Senate 1862-3. He wrote a valuable 'History of Rhode Island and Providence Plantations' (2 vols. 1860), and was for many years president of the Rhode Island Historical Society.

Ar'nold, Thomas, an English scholar, head-master of Rugby School, and professor of modern history in the University of Oxford: b. Cowes, Isle of Wight, 13 June 1795; d. 12 June 1842. He received the elements of his education at Warminster, and at the age of 12 was removed to the public school at Winchester. Having obtained a scholarship in Corpus

Christi College, Oxford, he entered that college in his 16th year, and though naturally of a shy disposition soon became remarked for the boldness and independence of his views, and the ability, firmness, and zeal with which he maintained them. In 1815 he was elected Fellow of Oriel College, and both in that year and 1817 obtained the chancellor's prize for Latin and English essays. His views had been early directed to the Church, but some scruples as to signing the articles made him hesitate for a time. At length these scruples gave way before a more careful examination, and he took deacon's orders in 1818. In 1819 he settled at Laleham, near Staines, where he employed himself in preparing young men for the universities, and in 1820 married the sister of one of his earliest school and college friends, Trevenen Penrose. About this time a remarkable change appears to have come over him; his religious views became finally settled, and his whole mind appears to have been wound up to a determination to use life diligently and earnestly for the best and holiest purposes. At Laleham he had much leisure, which he employed partly in the cultivation of general literature, and partly in writing articles on Roman history for the Encyclopædia Metropolitana, and collecting materials for an edition of Thucydides, whose writings, as well as those of Aristotle, had long been his favorites. In 1828, by the unanimous vote of the trustees, who were told on high authority that "he would change the face of education all through the public schools of England," he was appointed head-master of Rugby School, and devoted himself to his new duties with the greatest ardor. While giving due prominence to the classics, he deprived them of their exclusiveness by introducing various other branches into his course, and was particularly careful that the education which he furnished should be in the highest sense moral and Christian. His success was remarkable. Not only did Rugby School become crowded beyond any former precedent, but its pupils on removing to the universities carried off a very large proportion of prizes, and the superiority of Dr. Arnold's system became so generally recognized that it may be justly said to have done much for the general improvement of the public schools of England. In his position as a director of the London University he zealously endeavored to extend the benefits of a literary and scientific education to all classes and creeds without excluding religion; but failing in his efforts to make examination in the Scriptures requisite to obtain a degree, resigned his office. In 1841 he was appointed professor of modern history at Oxford, and delivered his introductory course of lectures with great success. The works by which Dr. Arnold will continue to be best known are his edition of Thucydides, his 'Roman History,' unhappily left unfinished, and his 'Sermons,' most of them prepared for his own chapel at Rugby, and so admirably adapted to the circumstances of the youths who formed the greater part of his audience, that, though written hastily and at broken intervals snatched from other labors, they are justly held to be models in their kind. See Stanley, 'Life and Correspondence of Thos. Arnold' (1860); Worboise, 'Life of Dr. Thos. Arnold' (1859); Fitch, 'Thomas and Matthew Arnold' (1897).

Ar'nold, Thomas, an English writer on literature, and editor of old texts, son of Dr. Arnold, of Rugby, and brother of Matthew Arnold: b. in Laleham, 30 Nov. 1823; d. 1900. He became a Roman Catholic, and spent a number of years in New Zealand and Tasmania. Among his works are 'A Manual of English Literature'; 'Select English Works of Wyclif' (3 vols., 1869); 'Selections from the Spectator'; 'Beowulf' (text, translation, and notes); 'Henry of Huntingdon'; 'Symeon of Durham'; and 'Chronicles of the Abbey of Bury St. Edmunds'; 'Passages in a Wandering Life' (1900). His daughter is the novelist, Mrs. Humphry Ward.

Ar'nold, Thomas Kerchever, an English educator: b. Stamford, 1800; d. 1853. He was educated at Cambridge University, became an Anglican clergyman; and published a large number of text-books for schools, including manuals for the Greek, Latin, French, and German languages.

Arnold of Brescia, är'nold ŏf brĕsh'a (*Arnaldo da Brescia*), an Italian religious and political reformer and agitator: b. about 1100; d. 1155. He was one of the disciples of Abelard, and on returning from Paris began to preach in his native city. In this way he stirred up the people against the clergy; and in France, whither he was forced to flee in 1139, he also found numerous adherents, for the immorality and arrogance of the clergy excited much discontent. The flame which he had kindled could not be extinguished by the excommunication pronounced against him and his adherents by Innocent II. He preached his doctrines in safety at Zürich in Switzerland till about 1144, when he appeared at Rome, where his eloquence occasioned among the people great disorder. The furious multitude, whom he himself could no longer restrain, revered him as their father, and even the Senate protected him till Adrian IV., in 1155, laid an interdict upon the city. This subdued the Romans, and Arnold was obliged to flee. He was taken in Campania, and executed at Rome and his body burned; his ashes were thrown into the Tiber, and his party was suppressed. His followers were known as Arnoldists.

Ar'nold of Winkelried, wĭng'kĕl-rēd, a Swiss hero, who, at the battle of Sempach, in 1386, sacrificed himself to insure victory to his countrymen. The Austrian knights, dismounted, had formed themselves into a phalanx, which the Swiss vainly strove to pierce, when Arnold, rushing on the spear points of the enemy, and burying several in his breast, thus opened a gap in the fence of steel. The Swiss rushed in through the opening, and routed the Austrians with great slaughter.

Ar'noldists. See ARNOLD OF BRESCIA.

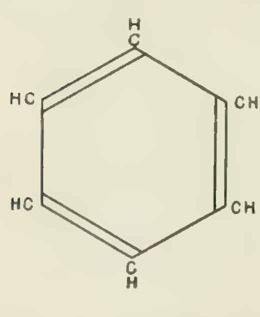
Arnprior, town of Renfrew County, Ontario, Canada; 38 m. by railway W. of Ottawa, on Canada Atlantic and Canadian Pacific Railways; at the confluence of the Madawaska River with the Ottawa. It is an important lumbering centre, and has other milling and manufacturing interests. The country round about is heavily wooded, and the abundance of water-ways especially favors the handling of timber. Pop. (1901) 4,152.

Arok-Szallas, ăr'ōk-säl'äsh, or Jasz-Arok-Szallas, a privileged market-town in Hungary, 44 miles northeast of Budapest. Pop. (1900) 11,190.

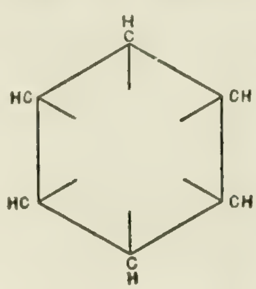
Arolsen, ä'rōl-sĕn, a German town, capital of the principality of Waldeck, on the river Aar. Rauch the sculptor was born here. Pop. (1900) 2,734.

Aro'ma, a Greek term denoting perfume. Many plants yield a more or less delightful odor, often due to volatile oils called essences, which can be separated from them by suitable processes. Sometimes odor proceeds from a substance which cannot be seized, and to which the name of *aroma* is more particularly applied. It appears that substances altogether, or almost altogether, inodorous may be made to diffuse a strong odor by the mixture of different substances which facilitate their volatilization. Thus, when musk is dried, ammonia is separated from it, and seems to be the vehicle of the odor, since the residuum becomes inodorous, and yet may again be made as odoriferous as it was at first by impregnating it with a quantity of the substance which had been carried off. Tobacco, in like manner, owes part of its odor to ammoniacal salts mixed with it in the process of manufacture. One singular fact is that many plants of tolerably strong odor yield an inodorous liquid when dissolved in water and yet communicate odor to the oils with which they are macerated. See Perfumery.

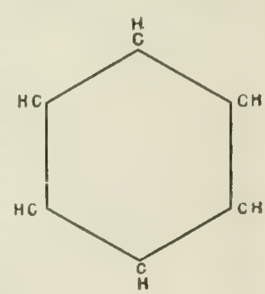
Aromatic Compounds, a numerous and exceedingly important class of substances, fundamentally differing from the fatty compounds in constitution, and named from the fact that the earliest known representatives of the class were resins, oils, and balsams, distinguished by a marked aromatic odor. The name is now applied to all substances containing a "benzene nucleus" (presently to be described). Benzene itself is the simplest example of an aromatic body. Its formula, expressed in the simplest way, is C_6H_6, but when the attempt was made to represent the composition of benzene by a "structural formula," numerous difficulties were encountered. For example, benzene behaves like a saturated compound in most respects, yet it contains eight atoms less of hydrogen than the saturated paraffin "hexane" (C_6H_{14}) containing the same number of carbon atoms. Again, any or all of the hydrogen atoms in benzene can be replaced by other monovalent elements (or radicals); and the persistence of the group C_6 in the derivations of benzene, even when all the original hydrogen atoms have been replaced by other elements or radicals, indicates that the carbon atoms in that body are intimately related to one another, in some manner. Furthermore, it has been proved by experiment that the hydrogen atoms in benzene are "of equal value," so that it makes no difference, in forming a substitution compound, which atom of hydrogen is replaced, and this fact indicates that the hydrogen atoms should occur in the structural formula symmetrically. To reconcile these considerations (and many others) Kekulé, in 1865, proposed for benzene the structural formula preceding.



The symmetry of the body with respect to hydrogen is here evident, and the persistence of the group C_6 is explained by assuming the six carbon atoms to be united to one another in the form of a closed chain, supposed to possess sufficient chemical strength to maintain its own integrity, save under exceptional circumstances. The closed ring of six carbon atoms is the "benzene nucleus," referred to above, which constitutes the distinctive feature of the aromatic compounds as a class. It will be observed that in Kekulé's structural formula the carbon atoms are all tetravalent, just as the carbon is in carbon dioxid (CO_2), and that three of the four valencies of each carbon atom are satisfied by the valencies of other carbon atoms, while the fourth is satisfied, in each case, by a hydrogen atom. Von Baeyer has proposed a slightly different structural formula for benzene, even more symmetrical in appearance than Kekulé's, but which raises certain questions that are not yet answered. His formula is as shown herewith.



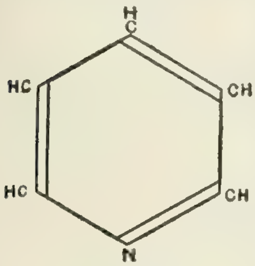
The closed carbon chain is present here also, but only three of the valencies of each carbon atom are definitely provided for, and it is assumed that the six remaining valencies (one to each carbon atom) are satisfied by a sort of "central linkage," whose precise nature is not determined or defined. It is customary, at the present time to express the structural formula of benzene in the simple form without attempting any explanation of the fact that the carbon atoms are here apparently trivalent. Much thought has been expended upon this matter, and the constitution of benzene is one of the most interesting problems in the realm of organic chemistry.



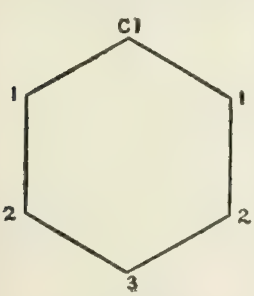
The structural formulas presented above are not to be taken in any sense as pictorial representations of the actual geometrical configuration of the benzene molecule. We know nothing at all about the shape of a molecule, nor about the way in which its parts are associated with one another, in space. The structural formulas employed in chemistry are mere empirical diagrams, for representing, to the eye, the chemical properties and relations that have been observed in the laboratory.

Compounds have been prepared which contain closed rings of three, four, and five atoms of carbon, respectively, but these are not classed as aromatic compounds. They are intermediate,

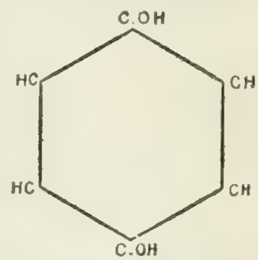
in general properties, between the aromatic series and the fatty series, but resemble the latter more closely. Compounds are also known in which the chain is closed by an atom of oxygen, or of sulphur, or of nitrogen. Thus the structural formula of pyridine is as shown herewith.



Such substances could be classed as "aromatic compounds" by an extension of the definition of the aromatic group, but are usually regarded as outside of the limits of that group. The aromatic compounds are so numerous, and include so many substances of technical importance, that only the merest outline of their general character can be given in this place. In general it may be said that they are derived from benzene by replacing one or more of its typical hydrogen atoms by an equal number of monovalent radicals (either simple or compound). The essential features of these substitutions may be illustrated by considering the chlorobenzenes. By the action of chlorine upon cold benzene, several substitution products are formed, having the formulas C_6H_5Cl, $C_6H_4.Cl_2$, $C_6H_3.Cl_3$, etc., according to the number of atoms of hydrogen that are replaced by the chlorine. The first of these substitution products, $C_6H_5.Cl$, is called simply "chlorobenzene," and it is to be noted that since the hydrogen atoms in the original benzene are all "of equal value" (that is, all involved symmetrically), it makes no difference *which* hydrogen atom is replaced by the chlorine; hence only one chlorobenzene having the formula $C_6H_5.Cl$ is possible. But when a *second* atom of hydrogen is replaced by chlorine, the resulting compound, $C_6H_4.Cl_2$ (known as *di*-chlorobenzene), can exist in no less than three distinct isomeric forms, according to the relative positions of the chlorine atoms in the benzene ring. For let the structural formula of chlorobenzene ($C_6H_5.Cl$) be represented by the skeletonized scheme the numbers representing the several groups of CH, in one of which the hydrogen is to be replaced by a further substitution of chlorine. It is evident that the next chlorine atom may replace a hydrogen atom at any one of the five vertices to which numbers have been attached; but it is also evident from symmetry that the two positions numbered "1" must be considered as essentially identical, so far as the product resulting from a substitution is concerned, and the same is also true of the two positions marked "2." Only three essentially different ways of substituting the second chlorine atom need therefore be considered. When the second chlorine atom is situated at an angle adjacent to the first, the product is known as *ortho*-dichlorobenzene;



when the second chlorine atom is separated from the first by one vortex which still retains its hydrogen, the product is known as *meta*-dichlorobenzene; and, finally, when the two substituted atoms of chlorine are *opposite* one another, the product is known as *para*-dichlorobenzene. The three different dichlorobenzenes thus shown by the structural formula to be possible, are actually known. All aromatic compounds having the general formula $C_6H_4Y_2$ (where Y is a monovalent radical) occur in three isomeric series, just as the chlorobenzenes do, and the separate compounds are distinguished, as already explained in the case of dichlorobenzene, by the prefixes *ortho-*, *meta-*, and *para-*. These prefixes are frequently abbreviated to single letters, in works on chemistry. Thus *p*- dihydroxybenzene is often written in the place of the full name, "para-dihydroxybenzene." This particular substance (used in photography and commonly known as "hydroquinone"), as its name implies, is formed by the substitution of two molecules of hydroxyl (HO) for two atoms of hydrogen in the benzene ring, the hydroxyl molecules being opposite each other (as indicated by the prefix *para-*). Its structural formula, therefore, is as below.



The ortho- compound having the same composition (except that its two hydroxyl molecules are in the "ortho" positions), is a different substance, known more familiarly as catechol, or pyrocatechin, and the meta- compound (where the two molecules of hydroxyl are in the "meta" positions) is quite different from either of the others, and is known as resorcinol. The substitutions of monovalent radicals for the hydrogen atoms in benzene are by no means limited to two, nor need the radicals that are substituted be alike. Thus the pyrogallic acid so extensively used as a developer in photography is obtained from benzene by the substitution of three molecules of hydroxyl for three molecules of the benzene hydrogen; and it therefore has the formula $C_6H_3.(OH)_3$. Vanillin, now largely used in the place of extract of vanilla for flavoring confectionery and ices, is benzene in which three atoms of the original hydrogen have been replaced, respectively, by the groups (CHO), (OCH_3), and (OH). On account of the typographical difficulties involved in printing the structural formulas of the aromatic compounds, chemists often specify the constitution of these compounds by numbering the original hydrogen atoms of the benzene from 1 to 6, and then specifying by number, which hydrogen atom has been replaced by each of the substituted radicals. Thus vanillin (referred to in the previous paragraph) consists of benzene in which CHO has been substituted for the first hydrogen atom, OCH_3 for the third, and OH for the fourth; and with this convention the constitution of vanillin may be expressed thus: $CHO : OCH_3 : OH = 1 : 3 : 4$.

The existence of tertiary (and higher) substitution products of benzene makes it possible to identify the ortho-, meta-, and para- di-substi-

tution compounds, so that the proper designation can be attached to each of them. The di-bromobenzenes afford a good example of the way in which this is accomplished. The three essentially different compounds obtained by substituting bromine for two of the hydrogen atoms in benzene are (according to the notation just given) Br : Br = 1 : 2, Br : Br = 1 : 3, and Br : Br = 1 : 4, these being ortho-dibromobenzene, meta-dibromobenzene and para-dibromobenzene, respectively. Now if an atom of hydrogen in the first of these be replaced by another atom of bromine, it is evident that the new bromine atom may have the position 3, 4, 5, or 6; but the compounds in which the bromine occupies the positions 1 : 2 : 3 and 1 : 2 : 6 must be regarded as identical, as will be seen by constructing the diagram; and, similarly, those in which it occupies the positions 1 : 2 : 4 and 1 : 2 : 5 must be considered identical. Hence the further introduction of bromine into ortho-dibromobenzene can give rise only to the two distinct tri-bromobenzenes 1 : 2 : 3 and 1 : 2 : 4. If the remaining dibromobenzenes be examined in the same way, it will be found that meta-dibromobenzene can yield (upon further bromination) the three distinct tri-bromobenzenes 1 : 2 : 3, 1 : 3 : 4, and 1 : 3 : 5. Finally, it will be found that para-dibromobenzene can yield only one tri-bromobenzene; namely, 1 : 2 : 4. The identification of a di-substitution bromobenzene as ortho-, meta-, or para- is therefore seen to be equivalent to determining how many different tri-bromobenzenes the given di-bromobenzene can yield. This problem has been fully worked out in the case here taken as an illustration, and it has been shown that of the three known di-bromobenzenes, the ortho- compound is the one boiling at 435° F., the meta- compound is the one boiling at 427°F., and the para- compound is the one melting at 180° F. The mode of identification here discussed in detail for bromine substitution products can be applied in other cases also, but the labor involved in the operation is so great that it is usually easier to ascertain the proper prefix for a new di-substitution compound by noting which of the bromo-substitution products must be used as a starting point, in the synthesis of the proposed compound. There is usually but little difference in the boiling points of ortho-, meta-, and para- compounds, but the para- compounds have the highest melting points. The benzene ring of ortho- compounds is liable to be broken up by oxidation, while in the other two classes the ring usually persists. The following general law appears to hold true of di-substitution aromatic compounds: When a radical is introduced into a benzene ring in which one hydrogen atom has already been replaced by a radical, the second radical will take a position "meta" to the first one, provided the first was COOH, SO_3H, NO_2, or (probably) CN, CHO, or $CO.CH_3$. In most other cases the second radical will mainly take the "para" position, though some of the "ortho" compound is almost invariably produced at the same time. The aromatic bodies include many acids, the simpler of which may be conveniently classified according to the number of molecules of carboxyl (COOH) that they contain, and according to the number of hydrogen atoms that have been displaced in the original benzene ring. The simpler and more familiar aromatic acids mostly contain one carboxyl group, and are therefore said to be "mono-carboxylic." In the mono-carboxylic group, benzoic acid, $C_6H_5.COOH$, is "mono-hydric"; salicylic acid, $C_6H_4.OH.COOH$, is "di-hydric"; proto-catechuic acid, $C_6H_3.(OH)_2.COOH$, is "tri-hydric"; and gallic acid, $C_6H_2.(OH)_3.COOH$, is "tetra-hydric." Numerous substances classed by the chemist as alcohols also occur in the aromatic group. The simplest of these (and the only one containing only six atoms of carbon) is phenyl alcohol, which is also known as phenol, and as carbolic acid. This substance is formed when benzene is oxidized by peroxid of hydrogen, in accordance with the equation.

C_6H_6	+ H_2O_2	=	$C_6H_5.OH$	+ H_2O.
Benzene.	Hydrogen peroxid.		Phenyl alcohol.	Water

Phenol is called an alcohol on account of its chemical structure (see ALCOHOL), but it differs widely from the alcohols of the fatty series, since it does not yield an aldehyde, an acid nor a ketone, and it is not easily oxidized. Other aromatic alcohols may be prepared by replacing a hydrogen atom in benzene by one of the alcohol radicals (C_nH_{2n+1}) of the fatty series, and then substituting an OH group for one of the hydrogen atoms in the compound so formed. The resulting substance has widely different properties, according to the position of the OH group so introduced. If the OH replaces a hydrogen atom in the alcohol radical, the final compound is called an alcohol; but if it replaces a hydrogen atom in the original benzene ring, the final compound is more accurately classed as a phenol. For example, if CH_3 be substituted for an atom of hydrogen in benzene, toluene ($C_6H_5.CH_3$) is formed. If, now, OH is substituted for a hydrogen atom in the CH_3, the resulting substance, $C_6H_5.CH_2OH$, is known as benzyl alcohol; while if the OH is substituted for an H in the original ring, we have $C_6H_4.(OH).CH_3$, a substance known as cresol, and more properly described as a phenol than as an alcohol. One of the most important members of the aromatic group is amido-benzene, or aniline (q.v.).

A. D. RISTEEN, PH.D.,
Editorial Staff, 'Encyclopedia Americana.'

Ar'omat'ics, plants (sometimes animal and other substances) which have a spicy odor and pungent taste and are used in medicine, cookery, and perfumery. They are largely employed to disguise the taste of drugs, are usually reputed stimulant, antispasmodic, and, if bitter, tonic and vermifuge; externally they are applied as antiseptics, local anæsthetics and counter-irritants. Their active principles are volatile oils obtained by distillation; but some contain camphor-like substances, such as turpentine; others are bitter like tansy; still others contain an odorous resin, for example, myrrh and benzoin; and lastly there are those with a musky odor, such as the musk plant (q.v.). Among aromatics and the families to which they belong are: peppermint, thyme, lavender, of the *Labiatæ* — the whole plant, especially the leaves; caraway, dill, anise, of the *Umbelliferæ* — the seeds or seed capsules; ginger, *Zingiberaceæ*—the root-stocks; cinnamon, cassia, of the *Lauraceæ Myrtaceæ* — the bark; cloves, *Myrtaceæ* — the flower buds; and vanilla, of the *Orchidaceæ* — the fruits.

Ar'omat'ic Vinegar, a liquid consisting of strong acetic acid, and obtained by distilling crystallized diacetate of copper. Its aroma is due to the presence of *acetone,* but it is also usually highly flavored with preparations, such as cloves, calamus, etc. It has a pleasant perfume, and its vapor, when inhaled, has a powerful effect on the nostrils, and acts as a strong excitant on the whole system. The liquid is highly corrosive.

Arona, ä-rō'nä, Italy, an ancient town near the southern extremity of Lago Maggiore. In the vicinity is the colossal statue of San Carlo Borromeo, 70 feet high, exclusive of the pedestal, 42 feet high. There are silk, cotton, and metal works here. Pop. (1901) 4,700.

Aroo. See ARRU ISLANDS.

Aroostook, a-roos'tŭk, a river in Maine. It rises in Piscataquis County, Me.; flows more than 120 miles in a circuitous course, and enters the St. John River in New Brunswick. It was an important factor in the settlement of the long-pending dispute concerning the boundary between the United States and British America.

Aroostook, Lady of The, the title of a book written by W. D. Howells in 1879 — one of the author's early works. The Aroostook is a trading vessel, and the lady of the story is the sole woman passenger in a voyage across the Atlantic. The story is strong and interesting, and contributed greatly to the early reputation of Mr. Howells.

Arouet, a'roo-ā'. See VOLTAIRE.

Around the World in Eighty Days, a noted romance by Jules Verne. Phineas Fogg, an English gentleman, wagers that a man can travel around the world in 80 days. He wins his wager, after a series of exciting adventures.

Around-the-World Records. Many years have elapsed since Mr. Phineas Fogg, M. Jules Verne's mythical hero, accomplished the supposedly impossible task of circumnavigating the globe in 80 days, a feat which won for him a wager of $100,000, and incidentally, a wife. Since that time, however, so many improvements have been made in methods of transportation, so many new routes — like that of the Trans-Siberian Railway (q.v.) — have been completed that Mr. Fogg's once remarkable trip now appears in the light of an extremely commonplace achievement. In fact the person who, to-day, could not travel around the world in less than 80 days would be regarded as a very inexperienced globe-trotter. The first serious attempt to lower Jules Verne's imaginary record was made in 1890, when Miss Nellie Bly, who represented the *New York World,* made the trip around the world against time. She was followed by the late George Francis Train, and both succeeded in accomplishing the tour in less than 70 days. Ten years later Mr. George Griffith, of Chiswick, England, established a new record at 64½ days, but this record stood for less than a year, it having been reduced, in 1901, to 60 days and 13½ hours, by Charles C. Fitzmorris, who made the trip at the request of Hearst's *Chicago American.* The success of Fitzmorris was the means of inspiring many persons to participate in this unique form of record breaking, among the contestants there being several journalists, the representatives of European and Canadian papers. All attempts to lower this last record were unsuccessful, however, until December 1903, when Mr. James Willis Sayre of Seattle, Wash., earned the honors for record breaking by girdling the globe in 54 days, 9 hours and 42 minutes, an achievement that lowered the Fitzmorris record by more than 6 days and 3 hours. Mr. Sayre's itinerary was as follows: From Seattle to Yokohama, Japan; thence by rail to Kobe, Moji, and Nagasaki, Japan; then by steamer to Dalny, Manchuria, and so on to Liverpool by what was practically an all-rail journey of 7,600 miles. At Liverpool he boarded a steamer for New York, and, two hours after his arrival in America, he was on a train bound west, for Seattle. This feat of lowering the world's record for globe-girdling was accomplished without the use of special trains, or boats, or any other method of travel beyond the means of the ordinary tourist.

Arpad, är'päd, the conqueror of Hungary, and founder of the Arpad dynasty, which reigned till 1301. He was born in the second half of the 9th century; died in 907. He was the son of Almus, whom the seven Magyar clans dwelling in the steppes northeast of the Caspian Sea had elected their hereditary chief about 889. Thus united into one nation, the Magyars, mustering about 25,000 warriors, crossed the Carpathians and conquered Hungary, when Arpad was elected their prince.

Arpeggio, är-pĕj'ō (Italian, from *Arpa,* a harp), in music, the playing of a chord on a keyed or stringed instrument by sounding the notes, not together, but in rapid succession.

Arpino, är-pē'nō (ancient *Arpinum*), a town of southern Italy, celebrated as the birthplace of Caius Marius and Cicero. It is situated on a rising ground near the river Garigliano, was originally founded by the Volsci, and became a municipal town under the Romans. It is still a place of some importance, possesses a royal college and several churches, and manufactures woolens. Pop. (1900) 10,607.

Arquebus, är'kwe-bŭs, an ancient species of firearm resembling a musket. It was fired from a forked rest, and sometimes cocked by a wheel, and carried a ball that weighed nearly two ounces. A larger kind used in fortresses carried a heavier shot. See ORDNANCE.

Arracacha, ăr'ra-kä'cha, or **Aracacha,** a genus of umbelliferous plants of Southern and Central America. The root of *A. esculenta* is divided into several lobes, each of which is about the size of a large carrot. These are boiled like potatoes and largely eaten in South America.

Ar'rack, or **Rack,** a name applied by Orientals to a strong spirituous liquor distilled from rice, from the juice of the cocoanut, date, and other palms, or from molasses. The arrack of Goa and Colombo in Ceylon is distilled from palm-juice alone, after being allowed to ferment; that of Batavia and Jamaica from rice and molasses. The rice is turned into malt by being soaked in water and allowed to sprout, after which the arrack is distilled from it on fermentation taking place in the same way as whiskey from barley-malt. The rice is also often used without being malted. The distillation of the fermented liquor affords the third or worst sort of arrack; this mixed with a little water and

again distilled gives the second best sort; a third distillation produces the best sort, which is seldom exported. The arrack sold in Europe is seldom genuine. Pure arrack is clear and transparent, with a yellowish or straw color, and a peculiar but agreeable taste and smell; it contains at least 52 to 54 per cent of alcohol. Not much of it is imported into England, but it is largely drunk in India and the East generally, the Indian and Pacific Islands, Africa, and South America. The arrack of Japan is known as saki.

Arragonite, a common but erroneous spelling for the mineral Aragonite (q.v.).

Ar'rah, a town of British India, in Bengal. The surrounding country is fertile and well cultivated, and near the town is a large and beautiful lake. It was rendered famous during the mutiny of 1857 by the heroic resistance of a body of 20 civilians and 50 Sikhs, cooped up within a detached house, to a force of 3,000 sepoys, who were ultimately routed and overthrown by the arrival of a small European reinforcement. Pop. 47,000.

Arrah Na Pogue, är-ra nä pōg, a play by Dion Boucicault. (q.v.).

Arraign'ment, in the practice of criminal law the calling of a prisoner by his name to the bar of the court to answer the matter charged upon him in the indictment. His innocence being presumed, it is the law, and is so laid down in the most ancient books, that, though charged upon an indictment of the gravest nature, he is entitled to stand at the bar in the character of a free man, without irons or any manner of shackles or bonds, unless there be evident danger of his escape, or of violence at his hands.

Arran, ăr'ăn, an island of Scotland, in the Firth of Clyde, 20 miles long, and 10 miles wide, with an area of 165 square miles. The island attains its loftiest summit in Goatfell, which is 2,900 feet high. The southern portion is rather hilly than mountainous, and contains several arable tracts of considerable extent and tolerable fertility. The geology of Arran has attracted much attention, as furnishing within a comparatively narrow space distinct sections of the great geological formations. The botany possesses almost equal interest, both in the variety and the rarity of many of its plants. Among objects of historical interest are the cave of Drumidoon, relics of Danish forts, and Druidical stones. Pop. (1900) 6,000. Consult 'A May Week in Arran' (1882).

Arras, är'ras', a town of France, capital of the department of Pas-de-Calais, in the middle of an extensive and fertile plain, on the Scarpe, which here becomes navigable. It is a well-built town, and has several handsome squares and a citadel, but is no longer fortified. The chief public buildings are the modern cathedral, the extensive buildings of the former abbey of St. Vaast, now accommodating a museum and the public library of 50,000 volumes; the Hôtel de Ville, one of the handsomest in the north of France, with a fine Gothic façade; the theatre, Hôtel de la Prefecture, barracks, etc. Its industries are varied and important. In the Middle Ages it was famous for the manufacture of tapestry, to which the English applied the name of the town itself. The corn-market of Arras is the most important in the north of France. It was the birth-place of Robespierre. Pop. (1900) 26,000.

Arrate y Acosta, är-rä'tā e a-kōs'ta, a Cuban historian: b. Havana, 1697; d. 1766. His history of Cuba entitled 'Llave del Nucoo Mundo y ante mural de las India Occidentales' remained in manuscript until 1830.

Arrawak, är'ra-wak. See ARAWAK.

Arrebo, är'rē-bō, **Anders Christensen,** a Danish poet: b. Aroöskjobing, 1587; d. 1637. He was made Bishop of Drontheim, Norway, when only 31, but deposed in 1622, owing to his objectionable life; he was afterward rehabilitated as preacher in Vordingborg. As the pioneer of the Renaissance movement, he is considered the father of modern poetry in Denmark. His rhymed translation of the 'Psalms of David' (1623), but especially his 'Hexameron' (1641), an imitation of a once famous poem of the French poet Du Bartas on the 'Creation,' are highly esteemed.

Arrest', the seizure of a suspected criminal or delinquent that security may be taken for his appearance at the proper time before a court to answer to a charge. Ordinarily, a person can be arrested only by a warrant from a justice of the peace; but there are exceptional cases in which he can be apprehended by an officer without a warrant, by a private person also without a warrant, or by what is technically called a "hue and cry."

Any peace officer, as a justice of the peace, sheriff, coroner, or watchman may, without a warrant, arrest any one committing a felony in his presence, 3 Hawkins Pl. Cr. 164; Tiner *v.* State, 44 Tex. 128; Reg. *v.* Chapman, 12 Cox. C. C. 4, or committing a breach of the peace, during its continuance, 3 Wend. N. Y. 384, or even to prevent the commission of a breach of the peace, Rex. *v.* Herns, 7 C. & P. 312, 32 E. C. L. 522, and such officer may arrest anyone whom he reasonably suspects of having committed a felony, whether a felony has actually been committed or not. 40 N. Y. 463; 25 Abb. N. C. 298; 3 Park. Cr. N. Y. 249; 99 Pa. St. 63.

A private person who is present when a felony is committed, 3 Wend. N. Y. 353; 1 Mood. 93; or during the commission of a breach of the peace, 10 Cl. & Fin. Hon. L. 28; 25 Vt. 261, may and should arrest the felon, and may upon reasonable suspicion that the person arrested is the felon, if a felony has been committed. 3 Wend. N. Y. 353; 6 Term 315.

An arrest is made by touching the body of the person accused. The object of arrest being to make sure that he answers to a charge about to be brought against him, it does not follow that after being seized he is incarcerated: if bail for his appearance at the proper time be given, and the case be not too aggravated a one for such security to be accepted, he will be released till the day of trial.

Arrest of Judgment, in law, is the act or process of preventing a judgment or verdict from being carried out till it shall be ascertained whether it is faulty or legally correct. Judgment may be arrested (1) when the declaration made varies from the original writ; (2) where the verdict materially differs from the pleadings and issue thereon; and (3) where the case laid in the declaration is not sufficient in law to admit of an action being founded upon it. A mo-

tion for arrest of judgment must be grounded on some objection arising on the face of the record itself. People *v.* Thompson, 41 N. Y. 1; People *v.* Kelley, 94 N. Y. 526. If the judgment is arrested all the proceedings are set aside, and judgment of acquittal is given, but this will be no bar to a new indictment.

Ar'rhenathe'rum, a genus of three species of tall perennial grasses closely allied to the oat (q.v.). *A. elatius* or *avenaceum* (also known as *Avena elatius* and *Holcus avenaceus*), which, as these names imply, bears a resemblance to oats, and sometimes called oat grass and French rye grass, is widely cultivated for fodder in France. True rye grass (*Lolium*) is, however, not a close relative.

Arrhenius, är-rā'nĭ-ŭs, **Svante,** a noted Swedish chemist: b. in Upsala in 1850. He was educated at the University of Upsala and after making many original investigations became professor in the University of Stockholm in 1891. His researches have been of the highest importance, the establishment of the theory of electrolytic dissociation being due to him. This theory supplies a reasonable explanation of many chemical phenomena otherwise insoluble and correlates various facts between which no connection has been previously discovered. He has published 'Sur la conductibilité galvanique des électrolytes' (1884), and a treatise in German on electro-chemistry (1902).

Ar'ria, a celebrated Roman matron, wife of Cæcinna Pætus, consul during the reign of Claudius, about 41 A.D. Pætus having raised an unsuccessful revolt against Claudius, in Illyria, was condemned to die, but was allowed the option of ending his life by suicide, which the Romans did not deem a crime. Pætus hesitated; Arria seized the dagger, plunged it into her bosom, and then presenting it to her husband, said, "It is not painful, Pætus."

Arriaga, är're-ä'ga, **Pablo José d',** a Spanish Jesuit: b. 1562; d. 1622. He was the first rector of the Jesuit College in Lima and wrote a valuable history entitled 'Estirpacion de la Idolatria de los Indos del Peni.'

Ar'ria'nus, a celebrated Greek historian, a native of Nicomedia, in Bithynia, who flourished in the 2d century under the Emperor Hadrian and the Antonines. He was a disciple of Epictetus, whose lectures he edited. While residing in Greece he gained the friendship of the Emperor Hadrian, who bestowed upon him the citizenship of Rome (124 A.D.), and subsequently appointed him prefect of Cappadocia. In this capacity he distinguished himself in the war against the Massagetæ. He was afterward advanced to the senatorial and even consular dignities. Like Xenophon, whom he imitated in style, he united the literary with the military character. His writings were numerous, but many of them have perished. His 'Anabasis' of Alexander the Great, still extant, narrates the Asiatic expedition of Alexander, and being based on the memoirs of Ptolemy Lagus and Aristobulus, who both served under that king, is proportionably valuable. To this is added a book on the affairs of India, which pursues the history of Alexander, but is not deemed of equal authority. An epistle from Arrianus to Hadrian is also extant, entitled 'Periplus Ponti Euxini' (A Voyage around the Euxine or Black Sea). There are also ascribed to him 'Treatise on Tactics'; and a 'Periplus of the Sea of Azof' and of the Red Sea, of which the authority is doubtful. We possess also his 'Enchiridion,' a moral treatise containing an abstract of the practical philosophy of Epictetus. There have been various editions of the 'Enchiridion' and the 'Anabasis.' His philosophical works have been translated by T. W. Higginson (Boston 1891) and the 'Anabasis' by Chinnock (1893).

Arrondissement, ä'rôṅ-des-mäṅ, a name given in France to the subdivision of a department, or of the quarters of some of the larger cities, as in Paris. The arrondissement is under the government of a Sub-Prefect.

Arroo. See ARRU.

Ar'row, a missile weapon, straight, slender, pointed, and barbed, to be shot with a bow. See ARCHERY.

Arrowhead, *Sagittaria,* a genus of plants of the natural order *Alismaceæ,* distinguished by unisexual flowers, having three herbaceous sepals and three colored petals, numerous stamens, and numerous carpels, which are compressed, one-seeded, and on a globose receptacle. They are aquatic plants, natives of very different climates, from the tropics to the cold regions of the world. The common arrowhead (*S. sagittifolia*) is a beautiful plant, a native of England, with arrow-shaped leaves which rise above the surface of the water. It is one of those plants which have enjoyed an undeserved reputation as cures for hydrophobia. The corms (or solid bulbs), dried and powdered, have sometimes been used for food, but have an acrid unpleasant taste. The Chinese arrowhead (*S. sinensis*) is a native of China, and has long been cultivated in that country and Japan for its eatable corms, which, in a fresh state, are somewhat acrid, but abound in starch. It has arrow-shaped acute leaves, and a branched polygonal scape (leafless stem). It is grown in ditches and ponds. It is one of the plants sometimes cultivated in tanks in hothouses.

Ar'row Lake, the name given to an expansion of the Columbia River, in British Columbia, about 95 miles long from north to south. It is often regarded as forming two lakes — the Upper and Lower Arrow.

Ar'row-root, a fine grained starch esteemed for making desserts and invalid foods. It is extracted from the underground parts of various tropical plants, especially of the genus *Maranta* of the natural order *Marantaceæ.* The popular name is said to be derived from the practice of the South American Indians who used the freshly dug rootstocks as an antidote for poisoned arrow-wounds. Probably, however, the derivation is from the Indian word *ara.* The principal species is *Maranta arundinacea,* indigenous to tropical America and cultivated in the West Indies, India and other warm countries. It is a perennial plant about two feet high, has small white flowers and fruits about the size and form of currants. The rootstocks, which often exceed a foot in length and three quarters of an inch in diameter, are yellowish white, jointed and covered with loose scales which must be carefully removed before the extraction of the starch, because they impart their disagreeable flavor if allowed to remain. The process of extraction, which is simple but usually crudely practised, is as follows: The root-

stocks are dug when a year old, well washed, peeled, beaten to a milky pulp in deep wooden mortars, and well washed to remove the fibrous parts, which are thrown away. The crude starch is next passed through a sieve or a coarse cloth and allowed to stand until the starch has settled, when the water is drawn and the white residue again washed. After again settling, the water is drawn off and the pulp when dried in the sun is reduced to powder. On a large scale arrow-root is manufactured with the aid of specially constructed machinery, but the process is essentially as described. Bermudian arrow-root is considered the best in the market, and next to it is that of Jamaica. The East Indian product is believed to be inferior, perhaps because of adulteration with or substitution of other starches, practices induced by the great demand and the high prices paid for the genuine. Some of these other starches are obtained from closely related plants, among which may be mentioned certain species of the genera Canna (q.v.), Curcuma (see TURMERIC), Manioc (see CASSAVA), Tacca (q.v.) and Arum. Potato, corn, rice and wheat starch and fine sago are also sold for arrow-root, but may be identified by miscroscopical examination; the form and markings of the starch grains differ from those of the arrow-root granules. When dry, arrow-root is odorless, but when damp has a slight smell. Like other carbohydrate foods, it is a source of energy, but since it is deficient in nitrogen compounds it should be mixed with eggs, milk, or other substances rich in nitrogenous materials, to form a well-balanced diet.

The amount of fecula or starch present in the roots of the *Maranta* varies according to age, and runs from 8 per cent, in those of the young plants, to 26 per cent when full grown. The latter stage is reached when the plant is 10 to 12 months old; and the roots then present the following composition in 100 parts.

Starch, fecula, or arrow-root	26
Woody fibre	6
Albumen	1½
Gummy extract, volatile oil, and salts	1
Water	65½

Arrow-root is exported in tin cases, barrels, or boxes, carefully closed up. It is a light, opaque, white powder, which, when rubbed between the fingers, produces a slight crackling noise, like that heard when newly fallen snow is being made into a snowball. Through the microscope, the particles are seen to be convex, more or less elliptical, sometimes obscurely triangular, and not very different in size. The dry farina is quite inodorous, but when dissolved in boiling water it has a slight peculiar smell, and swells up into a very perfect jelly. Potato starch, with which it is often adulterated, may be distinguished by the greater size of its particles, their coarser and more distinct rings, and their more glistening appearance. Refined sago-flour is used for adulteration, many of the particles of which have a truncated extremity, and their surface is irregular or tuberculated. Arrow-root is also sometimes adulterated with rice-starch and with the common starch of wheat-flour.

The starch of the cassava, manihot or manioc is sometimes imported into Europe under the name of Brazilian arrow-root. Potato-starch, carefully prepared, is sometimes sold as English arrow-root; and the farina obtained from the roots of the *Arum maculatum*, as Portland arrow-root. Otaheite arrow-root is the starch of *Tacca pinnatifida*. All these, as well as Oswego and Chicago corn-flour — the starch of maize or Indian corn — are so nearly allied to true arrow-root as not to be certainly distinguishable by chemical test; but the forms of the granules differ, so that they can be distinguished by the microscope.

Ar'rowsmith, Aaron, an English cartographer: b. Winston, 1750; d. 1823. He raised the execution of maps to a perfection it had never before attained. His nephew, John, b. 1790, d. 1873, was no less distinguished in the same field; his 'London Atlas of Universal Geography' may be especially mentioned.

Arroyo, är-rō'yō, the name of two towns of Spain, in Estremadura. Arroyo del Puerco, about 10 miles west of Caceres, has a palace of the old dukes of Benevente, and a parish church adorned with some paintings by Morales. Arroyo Molines de Montanches, about 27 miles southeast of Caceres, is noted as the scene of the defeat of the French, 28 Oct. 1811, by the British under Lord Hill.

Arru (a-roo') **Islands,** a group belonging to the Dutch, situated to the south of western New Guinea, and extending from north to south about 127 miles. They consist of one large island and a number of smaller. They are all low and swampy, but well wooded and tolerably fertile. The natives belong to the Papuan race, and many of them have been converted to Christianity by Dutch missionaries. The chief exports are trepang, tortoise-shell, pearls, mother-of-pearl, and edible birds'-nests, which they exchange for European goods. Agriculture is in a primitive state, but maize, sugar-cane, beans, bananas, etc., are cultivated. Sago is the chief diet, little animal food being eaten. Pop. about 15,000.

Arsaces, är-sā-sēz, founder of a dynasty of Parthian kings, who, taking their name from him, are called Arsacidæ.

Arsamas, är'sā-măs, a manufacturing town in the Russian government of Nijni-Novgorod, situated on the right bank of the Tiesha, 250 miles east of Moscow. It contains 34 churches, several convents and schools, 19 tanneries, several soap-works, linen factories, etc., and has a considerable trade. Pop. (1901) 12,380.

Ar'senal, a magazine, or place appointed for the making, repairing, keeping, and issuing of ordnance and other appliances required in warfare, whether in the army or navy. Sometimes the name is applied to an establishment where such articles are kept in store only, but the chief arsenals also embrace large factories or workshops. The principal arsenals of the United States are those in Allegheny, Pa.; Augusta, Ga.; Benecia, Cal.; Columbia, Tenn.; Fort Monroe, Va.; Frankford, Pa.; Indianapolis, Ind.; Kennebec, Me.; New York, N. Y.; Rock Island, Ill.; San Antonio, Tex.; Watertown, Mass.; and Watervliet, N. Y. There are also powder depots at St. Louis, Mo., and Dover, N. J.; a noted armory at Springfield, Mass., an ordnance proving ground at Sandy Hook, N. J. The Royal Arsenal, Woolwich, England, which manufactures warlike implements and stores for the army and navy, was formed about 1720. In France, each territorial military district (19 in all, including Algeria) has its own special arse-

nal or its own depot of war material. There are naval arsenals at the great government dockyards, namely Cherbourg, Brest, Lorient, Rochefort, and Toulon. The chief arsenals of Germany are situated at Spandau, Cologne, and Dantzig, that at the first-mentioned place being the great centre of the military manufactories. The chief Austrian arsenal is the immense establishment at Vienna, which includes gun-factory, laboratory, small-arms and carriage factories, etc. Austria also purchases quantities of her military stores from private manufacturers. Russia has her principal arsenal at St. Petersburg with supplementary arsenals elsewhere. In Italy, Turin is the centre of the military factories.

Ar'senic, an elementary substance, resembling the metals in its physical properties, and formerly classed with them. In its chemical relations, however, it is decidedly non-metallic, and at present the books mostly place it among the non-metals, though it is still customary to speak of the element itself as «metallic arsenic,» to distinguish it from the «white arsenic» of commerce, which is, properly speaking, an oxide of arsenic. Compounds of this element have been known for many centuries, chiefly on account of their poisonous character. The yellow sulphide of arsenic, otherwise called «orpiment,» was known to Dioscorides, who called it *arsenikon,* probably on account of its powerful properties; the Greek word *arsen,* from which it is derived, signifying «male.» Arsenic occurs in the metallic form in nature, usually with ores of iron, silver, cobalt, nickel, and antimony. Large masses of it are found at Zimeoff, in Siberia, and it occurs also in Saxony, Alsace, Bohemia, Transylvania, in the Harz, in Chile, in Japan, at Kongsberg in Norway and in parts of the United States. Combined with other substances, it is one of the most widely distributed of the elements, although the total amount of it in the world does not appear to be large. It occurs in various kinds of pyrites, and is therefore a common impurity in sulphuric acid (much of which is made from pyrites), and in substances in the manufacture of which this acid is used. The minerals known as kupfernickel (niccolite), realgar, orpiment, mispickel (arsenopyrite), and nickelglance (gersdorffite) contain it, as well as many others. The appearance of metallic arsenic varies greatly with the source from which it is obtained, and the method adopted for preparing it. That obtained from pyrites is usually compact, crystalline, and nearly white, while that obtained from arsenious acid is gray and pulverulent. The element is usually described as a «steel-gray metalline mass,» which, at ordinary temperatures, has neither odor nor taste. One chemist (Ludwig) obtained arsenic with «a perfectly bright surface, resembling freshly granulated zinc»; but it is doubtful if this was the pure element, since in preparing it he mixed with it a small quantity of iodine. For commercial purposes, metallic arsenic is obtained by refining the element as it occurs in nature, or by extracting it from arsenopyrite. The process of extraction from arsenopyrite consists in heating that mineral in earthenware retorts or tubes. arranged horizontally in a long furnace, and each having a piece of thin sheet-iron rolled up and inserted into its mouth. On distilling, most of the arsenic condenses on the sheet-iron, from which, after cooling, it may be detached. The product so obtained is further purified by mixing it with pulverized charcoal and re-distilling. The earthenware retorts that are used in the process are made with great care. They are composed of one part of fresh clay and two parts of pulverized bricks or old retorts, and are coated with a mixture of blood, loam, forge scales, and alum, which produces a glaze through which the poisonous vapors of the arsenic cannot penetrate. They are then fired. Arsenic is brittle and crystalline, and its hardness, on the mineralogical scale, is about 3.5. Its specific gravity ranges from 5.2 to 5.7, although a certain variety of it (according to Bettendorff) has a specific gravity as low as 4.71. It has several allotropic forms, one of which is crystalline, and the other black and amorphous. The specific heat of the crystalline variety is 0.083, and that of the amorphous variety is 0.076. Arsenic conducts electricity better than mercury does; for if the specific resistance of mercury at 32° F. be taken as unity, the specific resistance of arsenic is 0.373 at 32° F., and 0.534 at 212° F. The chemical symbol of arsenic is As, and its atomic weight is about 74.44 (Clarke). Its co-efficient of expansion is .000 00311 per degree F. Arsenic oxidizes slowly when exposed to the air, forming a gray powder which is sometimes sold under the name of «fly-powder.» It is not affected by pure water. When heated in the air it burns with a blue flame, giving off a characteristic, highly disagreeable, garlic-like odor. When protected from the air, metallic arsenic volatilizes at a red heat, without melting; its vapor being a light citron yellow, and phosphorescent. When heated under heavy pressure, arsenic melts at about 900° F.

Metallic arsenic forms alloys with many metals, some of which are produced by pulverizing and intimately mixing the constituents, and subjecting them to a pressure of 6,000 or 7,000 atmospheres. If much arsenic be present, the alloys are usually brittle. Arsenic is an undesirable impurity in iron, in general, but it is sometimes added to iron and steel for the manufacture of small chains and ornaments, because it makes the metal susceptible of a very brilliant polish. When alloyed with copper, arsenic gives a brittle gray metal, having a brilliant, silvery appearance, which is used somewhat for making buttons. The chief use of metallic arsenic, however, is in the manufacture of small shot. Pure melted lead, when dropped from a height, tends to form tailed drops; but if arsenic be added in small quantities this tendency disappears, and the drops are much rounder. With hydrogen, arsenic forms a very important gaseous compound known as arseniuretted hydrogen, or arsine, and having the formula AsH_3. This compound is best obtained by the action of sulphuric acid upon an alloy of arsenic and zinc. It is colorless, and so poisonous that Gehlen, its discoverer, was killed by inhaling a single bubble of it. Arseniuretted hydrogen burns with a bluish flame, and metallic arsenic is deposited upon a cold body that is held in the flame. Marsh's test for arsenic depends upon this fact. In executing this test, zinc and sulphuric acid are added to the solution to be tested, and the hydrogen evolved

is allowed to issue from a small jet, where it is lighted. A piece of cold white porcelain is then held in the flame, and if arsenic be present, the characteristic dark, metallic, mirror-like deposit will be produced, owing to the arseniuretted hydrogen that is evolved, simultaneously with the hydrogen. Antimony gives the same kind of a deposit, so that it is important to examine the deposit (or "arsenical mirror," as it is technically called,) to make sure that it is not composed of antimony. Marsh's test is extremely delicate, and will demonstrate the presence of incredibly small traces of arsenic, if proper precautions are taken to ensure absolute purity in the zinc and sulphuric acid that are used. Scheele's green (known chemically as "arsenite of copper") is a compound of copper, arsenic, oxygen, and hydrogen, of a light green color. It was formerly much used in calico printing and for wall paper. Schweinfurth green is a different compound of the same elements, and is used for similar purposes. A great diversity of opinion has prevailed among chemists as to the danger of using arsenical colors, especially in connection with wall papers. Some maintain that "there is no possibility of any arsenical exhalation arising from the walls, as has been alleged"; while others claim that certain microscopic fungi and other low forms of vegetable life act upon these coloring matters, and cause the elimination of arseniuretted hydrogen, which can actually be detected in the air of rooms hung with arsenical papers. Schweinfurth green is better known in the United States by the name "paris green," and is much used for preventing the destruction of crops by insects.

The most familiar compound of arsenic (with the possible exception of paris green) is undoubtedly arsenious oxide, As_4O_6 (often written As_2O_3), or "white arsenic," known to the general public simply as "arsenic." This is used extensively in the arts, in the manufacture of indigo blue and anilin; in glass-making, to remove the color due to the lower oxides of iron; in fly and rat poisons; in taxidermy; and for many other purposes. It is very poisonous, and in the 16th and 17th centuries was commonly used for removing persons who were conceived (by their enemies) to have outlived their usefulness. Nearly all the great poisoners of that period were women. In 1659 a secret society of young wives was discovered in Rome, whose chief object was to make away with the husbands of the members by the use of arsenical preparations. Hieronyma Spara, the woman who provided the members with the poison and instructed them in its use, was eventually executed, together with 12 others. An even more notorious case was that of the woman Tophania, who lived at Palermo and at Naples, and prepared, for wives who desired to be freed from their husbands, a poison known as *aqua Tophania.* This "aqua" purported to be an oil that oozed from the tomb of St. Nicholas of Barri; but as a matter of fact was an arsenical solution. "White arsenic" is not very soluble in water, and as four drops of Tophania's preparation were reputed to constitute a fatal dose, it is not unlikely that it consisted essentially of potassium arsenite, K_3AsO_3, a substance which is formed when "white arsenic" is dissolved in a solution of potash. Tophania plied her nefarious business from girlhood to the age of 70, but her crimes were ultimately brought home to her, and she was tortured and put to death. Detection almost certainly awaits the poisoner of to-day who uses arsenic, and a career such as Tophania's is absolutely impossible.

Ar'sen'ical Poisoning. Arsenic is now used in so many ways that accidental poisoning occurs very often. As a poison employed in committing suicide, and for slow poisoning with homicidal intent, its popularity is on the wane. The forms of poisoning mostly seen are of the chronic type. These occur from the use of paints containing large quantities of Scheel's green or Paris green; from the use of spraying solutions, now so widely employed as a means of protection from insect and fungus pests, and from the addition of arsenic to food stuffs, as a preservative. Acute forms of poisoning are more often the result of attempts to commit suicide. In acute arsenical poisoning the early symptoms are those of an acute inflammation of the stomach and intestines, coming on about half an hour after taking the poison. There are violent cramp-like pains, with nausea, vomiting, and diarrhœa, closely following the premonitory symptoms of distress, difficulty in swallowing, and constriction in the throat. The severe symptoms multiply, the diarrhœa becomes watery, "rice water" and blood may appear in the vomit. A cold, damp skin, weak and feeble heart-action, collapse and sighing respiration may precede death, attended at times with convulsions. Death may occur within 24 hours, but it is apt to be delayed from two to four days, the patient usually dying of the secondary degenerations in the organs and of exhaustion. Death by arsenic is very painful. It is, moreover, an extremely uncertain poison, because of its insolubility, and of the vomiting reaction it induces. Many acute cases pass over into the chronic stage of poisoning.

Chronic arsenical poisoning may result from a single large dose, but more often results from the long-continued use of small quantities of the poison. In a recent outbreak of chronic arsenical poisoning in Manchester, hundreds of people were affected. The source of the poisoning was from arsenic in iron pyrites employed in making sulphuric acid; this certain sulphuric acid had been utilized in the manufacture of glucose. Several firms had purchased this glucose for the manufacture of beer, and many hundreds of the consumers of this beer suffered from various forms of arsenical poisoning. Chronic arsenical poisoning may result from the use of wall-papers and hangings colored by arsenical dyes, although such modes of poisoning may be considered extremely rare. The symptoms of this type of poisoning are of gradual onset: the patient is languid, weak, and loses his appetite. There is discomfort in his intestines and diarrhœa or constipation may result. A sub-acute inflammation of the mucous membrane of the nose and gums then develops, with sore gums, puffiness under the eyes, and running from the nose. Sneezing, coughing, and hoarseness may occur, various skin eruptions are not uncommon, and a curious pigmentation of the skin is nearly always observed. The patients progress until poisoning of the ends of the nerves begins, with disturbances in sensation,

anæsthesia, paresthesia, and pain. There may then develop paralysis of the extremity, frequently the toe, (drop-toe); or the wrist, (drop-wrist). Paralysis of sensation may also occur. The course of a chronic poisoning may not be over three or four days, but it usually requires three or four weeks, sometimes longer. Some individuals use arsenic throughout their lives and are never poisoned. The treatment of acute poisoning consists in the thorough and prolonged washing out of the stomach and the use of large quantities of magnesia. Supportive treatment is needed in the stage of collapse. Heat, alcohol, and coffee are indicated. In chronic poisoning electricity and tonic treatment are required.

Arse'nious Acid, the arsenical compound familiarly known and popularly called arsenic. It is obtained principally during the roasting of the arsenican nickel ores in Germany in furnaces communicating with flues. The ordinary arsenious (which is what is popularly known as arsenic) is a white crystalline powder, decidedly gritty, like fine sand, and with no well-marked taste. It is very heavy, so much so as at once to be noticeable when a paper or bottle containing it is lifted by the hand. It is soluble in water, to the extent of 1 part of acid in about 100 parts of cold water, and 1 part of acid in about 10 parts of boiling water. When placed in a spoon or other vessel and heated, it volatilizes and condenses in crystals on any cool vessel held above. By this means it can be distinguished from ordinary flour, which, when heated, chars and leaves a coal behind; and from chalk, stucco, baking-soda, tooth-powder, and other white substances, that when heated, remain in the vessel as a non-volatile white residue. In some countries, as in the mountainous regions of Austria, Styria, and the Tyrol, arsenic is eaten habitually, beginning with small doses and gradually increasing them. It is said to favor nutrition, and to improve the respiration in ascending heights. Some of the «arsenicophages» can take great quantities with impunity.

Arsen'olite, a native trioxide of arsenic, having the formula As_4O_6 (often written As_2O_3), and crystallizing in the isometric system,— usually in octahedrons. It is commonly white, with a vitreous lustre. Its hardness is 1.5, and its specific gravity about 3.71. It occurs in connection with ores of silver and lead, and with those of other metals when arsenic is associated with them. In the United States it has been found in Nevada and California. Arsenolite and senarmontite (an antimonial mineral of analogous composition and similar crystalline form) are collectively known by mineralogists as the «arsenolite group.»

Arsenopy'rite, ar-sen-o-pī'rīt («arsenical pyrites»), a tin-white, opaque mineral, with a metallic lustre, crystallizing in the orthorhombic system. It contains arsenic, iron, and sulphur, and has the formula FeAsS. Its hardness varies from 5.5 to 6.0, and its specific gravity from 5.9 to 6.2. Arsenopyrite is largely used as a source of «white arsenic,» or arsenic trioxide. It occurs chiefly in the crystalline rocks with gold and ores of silver, lead and tin. It abounds in Germany, England, and the United States.

Arsinoë, är-sĭn'ō-ē, the name of several celebrated women of antiquity, the most noted of whom is the daughter of Ptolemy I. of Egypt and Berenice: b. about 316 B.C.; she married Lysimachus, king of Thrace, in 300 B.C. Desirous of securing the crown for her own children, Arsinoë prevailed upon Lysimachus to put Agathocles, the son of his former wife, to death. This crime proved fatal to the Thracian king; for Lysandra, the wife of the murdered prince, fled with her children to the court of Seleucus Nicator of Syria, who took up arms in her favor. In the course of the war Lysimachus was slain and his kingdom taken possession of by the conqueror. Arsinoë now fled into Macedonia, which was soon overrun by the Syrian army. In less than a year afterward, however, Seleucus was assassinated by Ptolemy Ceraunus, half brother of Arsinoë. This queen, who held the city of Cassandria in Macedonia, was induced, under promise of marriage, to admit Ptolemy within its walls; but no sooner had he entered than her two children were butchered before her eyes. She succeeded in making her escape to Egypt, where she became the wife of Ptolemy II., Philadelphus, her own brother (279 B.C.), thus affording a precedent to these unnatural unions which afterward became common among the Greek rulers of Egypt. She bore no children to her brother, who, however, seems to have had a strong affection for her, as he called one of the districts of Egypt by her name and employed the architect Dinochares to build a temple in her honor.

Arsin'oë, a city of ancient Egypt, on Lake Mœris, said to have been founded about 2300 B.C., but renamed after Arsinoë, wife and sister of Ptolemy II., of Egypt. The site of Arsinoë is now occupied by the town of Medinet-el-Faium. The sacred crocodiles were kept here.

Ar'son, the malicious and wilful burning of a dwelling-house or out-house belonging to another person by directly setting fire to it, or even by igniting some edifice of one's own in its immediate vicinity. If a person, by maliciously setting fire to an inhabited house, cause the death of one or more of the inmates, the deed is murder, and capital punishment may be inflicted. When no one is fatally injured the crime is not capital, but is still heavily punishable; it is a penal offense also to attempt to set a house on fire, even if the endeavor does not succeed. The New York Penal Code provides that a person who wilfully burns, or sets on fire in the night-time, either (1) a dwelling-house in which there is, at the time, a human being; or (2) a car, vessel, or other vehicle, or a structure or building other than a dwelling-house, wherein, to the knowledge of the offender, there is, at the time, a human being, is guilty of arson in the first degree.

Many statutory changes have been made in the common law upon this subject. There are three degrees of arson in the State of New York. Arson in the first degree is punishable by imprisonment for any term not exceeding 40 years; in the second degree by imprisonment for a term not exceeding 25 years; in the third degree for a term not exceeding 15 years. Before the crime of arson is complete, the house, or some portion of it, however small, must be burned, or consumed by fire.

Art, in its most extended sense, as distinguished from nature on the one hand and from science on the other, has been defined as every

regulated operation or dexterity by which organized beings pursue ends which they know beforehand, together with the rules and the result of every such operation or dexterity.

In æsthetics, art as distinguished from science, consists of the truths disclosed by that species of knowledge disposed in the most convenient order for practice, instead of the best order for thought. Art proposes to itself a given end, and, after defining it, hands it over to science. Science, after investigating the causes and conditions of this end, returns it to art, with a theorem of the combination of circumstances under which the desired end may be effected. After receiving them, art inquires whether any or all of those scientific combinations are within the compass of human power and human means, and pronounces the end inquired after attainable or not. It will be observed here, that art supplies only the major premise, or the assertion that the given aim is the one to be desired. The grounds of every rule of art are to be found in the theorems of science. An art can then consist only of rules, together with as much of the speculative propositions as comprises the justification of those rules. Though art must assume the same general laws as science does, yet it follows them only into such of their detailed consequences as have led to certain practical rules, and pries into every secret corner, as well as into the open stores of the household of science, bent on finding out the necessities of which she is in search, and which the exigencies of human life demand. Hence, as Edmund Burke remarks, in his 'Treatise on the Sublime and Beautiful,' «Art can never give the rules that make an art.» It must always owe them to science. Whatever speaks in precepts or rules, as contrasted with assertions regarding facts, is art; and hence it always adopts the imperative mood, whereas, science almost invariably adopts the indicative. Science is wholly occupied with declarations; art is wholly engaged with injunctions that something should be done. Thus, the builder's art desires to have houses, the architect's art desires to have them beautiful; and the medical art desires to cure diseases of the human body.

In a special sense art is the practical carrying out of the principles of science; a series of rules designed to aid one in acquiring practical skill or dexterity in performing some specified kind of work, manual or mental. The several arts may be arranged in two groups — (a) the mechanical, and, (b) the liberal or fine arts. The mechanical arts are those which may be successfully followed by one who does not possess genius, but has acquired the facility of working with his hands which long practice imparts. Such are the arts of the carpenter, the blacksmith, the watchmaker, etc. They are often called trades. The liberal or fine arts are such as give scope not merely to manual dexterity, but to genius; as music, painting, sculpture, architecture, etc.

In mediæval education, the arts signified the whole circle of subjects studied by those who sought a liberal education. This included science as well as art. The seven liberal arts, which, in the palmy days of Rome, plebeians were not allowed to study, were thus divided: (1) the *Trivium* — namely, grammar, rhetoric, and logic; (2) the *Quadrivium* — namely, arithmetic, music, geometry, and astronomy. It is a remnant of this classification, which was in vogue as early as the 5th century, that we still speak of as the curriculum of arts at a university, and that graduates become bachelors or masters of arts. See ARCHITECTURE; MUSIC; PAINTING; SCULPTURE, etc.

Art, American'. The art history of America presents interesting conditions of receptivity, as well as original productivity; indeed, artistic taste, it may be claimed, was primarily transplanted or transfused into the budding art of «The Fair New World.» True to the traditions of historical repetition, the ideals of ancient Greece inspired an Italian renaissance; French, German, and English art respectively, being viewed moreover at their best periods, give evidence of having been begotten through æsthetic assimilation and fruitful appreciation of the masterpieces of Angelo, Titian, Tintoretto, Rembrandt, Rubens, Veronese, and Velasquez. The early American school not only emulated these treasured qualities of the old masters, as far as accessible in painting and sculpture of originals or in replicas, but experienced a healthful art evolution, normally stimulated by the contemporary works of Gainsborough, Reynolds, Lawrence, and others, at the close of the 18th century. It appears in accord with the artistic spirit of international reciprocity, that America provided the British Royal Academy with its second president in the personality of Benjamin West.

Although it would be intensely interesting to explore the field of Pan-American art, revealing Aztec and other aboriginal archæological relics, we are limited to the consideration of the subject co-incidental with modern art and civilization. The works of Washington Allston, Gilbert, Stuart, West, Copley, Trumbull, Vanderlyn, Jarvis, Peele, Cole, Harding; and, at a later period, of Morse, Eliot, Mount, and many others, afford invaluable examples of rare intrinsic value, with chronological evidences of the early development, impeded by all sorts of obstacles, of inborn genius and unmistakable tendencies of the American progressive element even in the province of fine art. A representative collection of the famous works by the American painters mentioned, had it been secured, would certainly to-day constitute a rare gallery of æsthetic «Americana» that well might be preserved for all time — «*con amore*» — «*pro patria et gloria*»; enkindling American art patriotism in line with that shown for the army and navy, agriculture and commercialism. It is too late, however, to secure the marvelous masterpiece by Allston, 'The Legend of the Bloody Hand,' it having unfortunately been destroyed by fire, and many other gems of renown are now lost sight of, through lack of proper preservation and of popular appreciation. Vanderlyn's 'Ariadne,' however, has fared better in company with invaluable portraits, painted by these gifted men and now in possession of the New York Historical Society. 'Marius Sitting Among the Ruins of Carthage,' a work that secured Vanderlyn, in reward for its merits, a first-class gold medal at the Paris Exposition, was a product of this period. The most important epochs of American history have been represented by native artistic talent. The sailing and landing of Columbus, the exploits of De Soto, the subju-

gation of savage life to that of civilization, Colonial and Indian warfare, the declaration of national independence, Revolutionary battles, Washington crossing the Delaware, and like famous subjects for painting and sculpture, that manifestly should be preserved by governmental direction. Although so long and disastrously belated, these facts and conditions logically suggest the formation of a national gallery of American art. The landscapes of Thomas Cole upheld, as did those of Turner, the traditions of Claude Lorraine; still in the spirit of a pioneer he proclaimed the grandeur of the primeval American forest in paintings direct from nature. His 'The Course of Empire,' now in possession of the New York Historical Society, a work that has never, we believe, been reproduced in any form, presents in four grand paintings the sway of civilization from savage life to an Arcadian period; then onward to the consummation of earthly power and magnificence; followed by the decadence occasioned by war of the elements, and that instigated by "man's inhumanity to man"; finally, the literal scene of monumental destruction and sublimely solemn desolation. Before dismissing attention called to this early period influenced, as stated, by foreign methods of technical expression, native American genius found little public appreciation; still it faithfully progressed. Again about this time matter-of-fact utilitarianism appeared to dispel the ideal artist's poetic hopes, while every encouragement followed the success of practical scientific talent. Washington Irving essayed to be a painter, but concluded to devote his life to literature and the power of the pen. Robert Fulton, who began his career as a skilful landscape and portrait painter, attracting the friendship of Benjamin Franklin, who encouraged his studies abroad, and gave him letters to Benjamin West and others, returned to his native land to find that scientific conditions were required rather than a demand for the credentials of culture in works of fine art. The result was steamboat navigation. Another triumph for science may be recorded. Franklin himself had captured lightning from the skies; still it remained for the imagination and artistic skill of the professional painter, Samuel Finlay Breese Morse, the first president of the National Academy of Design, to subjugate the marvelous electric element that joins as neighbors all mankind.

Nevertheless, the fine arts flourished; even modern travelers' tales of the wonderful scenery of two great continents stimulated artists and the lovers of art. "The Heart of the Andes," "Niagara," "The Arctic Region," "The Rocky Mountains," "The Catskills," "Lake Champlain," "Lake George," and the "Hudson River," all were delineated. Along with this demand for great subjects, often commensurate in quantity as to size of canvas with Ruskin's mathematical maxim: that the greatest work of art is the one presenting the greatest number of great ideas; there still prevailed in marked instances the glorious traditions of full-habited oil-painting to be found in the æsthetics of familiar environment of earth, air, and water, as embodied in artistic values and soulful qualities — creations in harmony with Michel, Ruysael, Constable, and the masters of Barbazon and Fontainebleau. Again, while scientific influences appear in the works of Durand, Church, Casalear, and Kensett, they asserted a truly American artistic individuality; they copied directly from nature. They thought of no school nor technique, but carefully imitated what they saw. All these men with one exception had been practical engravers, laying down the burin and the needle-point to take up the pencil and the brush. Their respective biographical and æsthetical records in American art will be enduring; yet there comes the reflection that had their professional training been more liberal and adequate they would have attained to higher things. The importance of masterly academic training cannot be overestimated; as a means to an end, however great, education is the only acknowledged guide for the individual artist and for the community even in matters of taste. Nothing is more creditable to a civilized people than its credentials of culture. The formation of a fine art association in its chief city was at the beginning of the past century an occasion of vast importance to our commonwealth. The first action was taken in 1802 by a few prominent citizens, and six years later a charter was obtained with the name of The American Academy of Arts. The first officers under this charter were Robert Livingston, president; John Trumbull, vice-president; DeWitt Clinton, Dr. David Hosack, John R. Murray, William Cutting, and Charles Wilkes, directors. A school was equipped with casts brought from Paris by Mr. Livingston, and exhibitions of paintings and statuary were held for a time in an unused riding school in Greenwich Street near the Battery. Public interest in this movement was soon transferred to grand panorama schemes conducted by Vanderlyn at the "Rotunda," and by others with similar enterprises. It was not until the year 1826 that the artists themselves, with Morse as president, founded the National Academy of Design in the earnest interests of American art, with educational purposes and exhibitional facilities; its influence increasing until the present day. Its membership consists of one hundred academicians and an equal number of associate members, including the most distinguished painters and sculptors of America. Its list of fellowship for life likewise includes the most prominent public-spirited patrons of American art.

Established for many years in the Academy building, tastefully modeled after the Palais Ducal of Venice and forming an attractive urban landmark, lack of accommodations for its growing schools, and crowding commercial surroundings, required a move to more suitable quarters. Unlike the Royal Academy of London, with its plethoric treasury, and similar institutions situated in other European art centres, the academy is without governmental endowment, and may well enlist American art patriotism in the cause of æsthetic culture in fostering the fine arts of painting, sculpture, and architecture. Other societies of American artists, water color societies, and architectural leagues make annual exhibitions in New York; while art institutes throughout the United States, in various cities attest the extent and importance of American art. We, as Americans, are an artistic people, cosmopolitan, and composite, uniting the genius of all nations. The æsthetic field of general American artistic taste and industry has been strenuously productive. The

ornamental, orderly, and decorative work in clay, on china, glass, wood, and stone as a tasteful and profitable divertisement, begins with the training of the kindergarten. Black and white illustration and etching has been awarded first-class medals at home and abroad. The beautiful and refined exemplified in aguarelle and oil-painting, in portraiture, genre, and pastoral; in sculpture and architecture; and finally the grand and sublime of high art, all confirm the achievements of American art and artists.

In advancing these three divisions,— the ornamental, the beautiful, and the sublime,— as a guide, we approach the philosophical consideration of the subject of fine art. What is, and what is not, fine art? Shakespeare's injunction "to hold, as it were, the mirror up to nature" is the best artistic advice ever given. Bacon in his essay is not so direct. He asks which is the greater trifler, one who would make a personage by geometrical proportions (perhaps by the fabled Greek cabala) or another who would select the best parts of divers faces to make one excellent (a veritable composite picture)? He concludes at last that: a painter may make a better face than ever was, but he must do it by a kind of felicity, as a musician who makes an excellent air in music, not by rule. If ever there was an artist he was Shakespeare — if ever there lived a scientist, Lord Bacon was, perhaps, the most eminent, and in their respective views and definitions we find the differentiation between science and art. In any given work in so far as it may be mechanically constructed is presented a scientific product; and in so far as reproductive processes may exhaustively duplicate it, it falls short of the possibilities of fine art. An etching by a master may be an autographic art creation; but when it is possible through photography, photo-gravure or chromo-lithography to so perfectly duplicate a painting, that the reproduction presents all the merits of the original, it may be realized to science rather than be accepted as genuine fine art. True consummate mechanism must ever go hand in hand with fine art; still a great work of art presents the maximum of art to the minimum of mechanism. A painting portraying living objects with a sharp contour, such as may delight the photographer, without the suggestive quality of stereoscopic relief, does not hold the mirror up to nature, and the work may be classed with scientific achievements even if accredited to the consummate mechanism of a Messonnier. Indeed reproductive processes have served a great purpose in defining the line of demarcation between science and art. Affectations have been swept away by a revelation of their superficiality; while the possibilities of inimitable fine oil-painting, a medium and technique that, of all ever employed, has the fewest possible limitations, have been enhanced as seen in the works of the American artists already mentioned; and in those of a growing group of American idealists, colorists, and tonalists. Various have been the fashions or "isms" that have dominated American art at different periods of its history. Preraphaelitism as advocated by Ruskin was one of the earliest imported. Being appointed the legal executor of his hero-client, as well as being an enthusiastic admirer of his work, Ruskin claimed for Turner not only the grander qualities, but a command of detail that rivaled the ancients, although the artist, we are told, frankly declined the compliment. Turner was unquestionably the greatest modern master of decorative and scenic effect in pictorial combinations representing earth, air, and water, being, indeed, entitled to the apotheosis of synthesis; still diligent search in the archives of the Royal Academy and National Gallery fails to reveal the qualities attributed to him by the author mentioned. Ruskin's enthusiasm proved contagious throughout the art circles of England and America; solicitous friends as well as the most influential art writers pleaded with the tyro to emulate not the work of Michael Angelo, Titian, or Raphael himself, but to follow in the footsteps of Perugino and Raphael's father or grandfather. This verily seemed like unto the dotage of imbecility in the light of Raphael's glorious art that had evolved the immaculate Sistine Madonna. He was brave, indeed, in the field of American art of that day, who could resist the popular and professional pressure of this pseudo-æsthetic movement. No vestige of it remains, and no wonder it was followed by impressionism — as a free and joyous transition from mechanical restrictions in art. This was the artistic attempt to present the maximum of soulfulness conveyed to the world by finest art; employing the minimum of materiality and mechanism as seen in the rendition through mental vision of the fleeting sunset or twilight — such as may only be materialized on the morrow; the epitomization perhaps of a day's outing under the open skies or flying clouds, or in the sublime thunder-storm; in fact, the entire realm of imagination is unfolded by artistic impression. Such was the accepted province of genuine impressionism originally as associated with the artistic convictions and poetic spirit of Corot, Monet, Monticelli, William Hunt, William Page, George Fuller, and many others. Impressionism naturally evolves symbolism and idealism, but in too many instances has deteriorated into affectation and mysticism. Premeditated and assumed mysticism is the *dernier-ressort* of mediocre painters and sculptors, as well as of the minor poets. It may not be mistaken for sublime spirituality. Dante, Shakespeare, and Milton, treating even divine themes, never nebulized their ideas in mysticism; the same may be said of Bryant and Longfellow; while Poe, temperamentally, a mystic solitudinarian, in the field of poetic art presented the apotheosis of spirituality.

The crowning glory in the art of any civilized country is that of naturalism. In the truest sense it utilizes even scientific "disjecta membra," as enumerated, and subjugates the same to the entirety of art. The comprehensive structural organic presentation of material nature, suggesting the qualities of size, form, weight, color, and perspective values; chiaroscuro, and, above all, the ultimatum of expression and tone. These enduring qualities characterize the art of Innis, Martin, Wyant, Hunt, and Page, and the growing group of American tonalists of the naturalistic school. A great advantage exists in American art from its cosmopolitan resources. In Paris one sees nothing but French art; in Munich, the German school; in London, English art, while the art institutions of America contain specimens of masterpieces from every

source, notably the collection of the Metropolitan Museum of Art, and art institutes of Brooklyn, Boston, Chicago, Philadelphia, and Pittsburg, as well as collections in all our large cities. While every art centre of Christendom seems to be provided with an American colony of artists and students, expatriation is no longer a necessity in order to obtain an education in fine art. The Academy and various art student leagues are conducted by eminent instructors distinguished with every honor obtainable at home or abroad. The prospects of a greater appreciation of American art open with the new century, as interest in the pursuits of peace should naturally follow national expansion. Advocacy of our chief art educational institutions is a feature of metropolitan aggrandizement; millions have been given to libraries and various institutions of learning; and fine art should be included with erudition, as the essential credential of culture. Timely attention may be called to the requirements of the pioneer American art institution, founded by the immortal Morse and his co-workers eminent in art instruction, and being associated with the career of America's greatest masters in painting, sculpture, and architecture. In accord with urban expansion it has departed from its classical landmark, a diminutive «Palais Ducal,» to a most accessible and beautiful site, upon the acropolis of the metropolis, facing Cathedral Driveway, Morningside Park, New York city. As the leading exponent of American art instruction, through schools and exhibitions, it is planned to erect an edifice that shall do justice to the artistic taste of the New World's metropolis, and to the original National Academy of Design.

The Department of Commerce just established by the general government is a step in the right direction of national affairs, and may make clear the way for the proposed Department of Art and Industries. It has been repeatedly advocated and constant evidences of its requirement as an absolute necessity have been presented to the government and to the people; still it is being detrimentally delayed. The appropriations for national and international expositions have repeatedly been used in a manner giving anything but satisfaction. Commissions and contracts for statuary, monuments, and architecture that should receive the supervision of expert art judgment are left to provisional committees of statesmen, who frankly admit their inability to judge in the affairs of fine art. The disastrous experiences resulting from this careless management of each and every international exposition, including the Centennial, the New Orleans, the Chicago Columbian, and the Buffalo Pan-American, certainly teach that no similar enterprise should be thrust upon the community for co-operation through flattering prospectuses, promises of profit, etc., until matured and definite plans and specifications shall have been officially inspected, approved or rejected by the projected national department of art and industries; this would also provide a valuable bureau of information in art affairs, enabling legislator and citizen to act or vote intelligently in regard to any appropriation, commission or tariff. The practical utility and public good to be derived from such a department may be demonstrated in many instances. A member of Congress having been appointed upon a committee assigned the duty of supervising the ground immediately surrounding the House of Representatives was astonished to find that millions of dollars had been expended upon the same; each new committee annually appointed having exercised its taste and judgment on the important matter. It was concluded that the advice of an expert landscape architect be secured, and this being done, the expenditure was practically ended. Again the enormous expense of indiscriminate illustration of congressional and department literature or printed matter has, to-day, caused anxiety and criticism. So in relation to all official cases requiring expert art supervision, eclectic sense and æsthetic taste should be at the service of the government. The plan involves no untried innovation; the French nation has its Minister des Beaux Arts, who is a member of the Cabinet of the Republic of France, leading the world in art affairs, taste and fashion. The establishment of Municipal Art Commissions is a step in the right direction. The task of correcting the contour of metropolitan architecture seems, indeed, herculean; individual buildings of great beauty are adjoined by the most heterogeneous structures; a three-story house appears between one of eight and a sky-scraper of twenty. In no capital of Europe would such incongruities be permitted, and every possible facility should be afforded our Municipal Art Commissions to correct this chaotic condition. Victor Hugo said «the beautiful is as useful as the useful, more so, perhaps.» European municipal politics profit by the practical application of this fact; great cathedrals, public statuary, and fountains, picture galleries and museums attract multitudes of tourists, thereby financially as well as æsthetically benefiting communities that keep in the vanguard of culture and civilization.

Art, History of. See FINE ARTS.

Art, Metropolitan Museum of, a spacious edifice in Central Park, New York, erected by the city for the purpose to which it is devoted. It was incorporated in 1870, and possesses an art collection amounting in value to over $2,000,000, including the Cesnola collections. The treasures to be found here are various in character and of most profound interest, especially the ancient sculptures and relics from the island of Cyprus. These, in the study of antiquities, are of much value, and many of the other departments likewise possess rare attractions.

Art of Poetry, The ('Ars Poetica'), a famous work by Horace. This is not the name given it by its author, who called it merely a

‹Letter to the Pisos.› Horace treats of the unity that is essential to every composition, and the harmonious combination of the several parts, without which there can be no lasting success. In the second part, the poet confines himself to the form of the drama, the principles he has already established being so general that they apply to every class of composition.

Art Unions, a name applied to associations for the encouragement of the fine arts by the purchase of works of art out of a common fund raised by small subscriptions or shares, and their distribution by lot. The first art union was started in France; but the Munich art union was the first of importance. Berlin and other towns of Germany soon followed the example of Munich, and the first art union was founded in Edinburgh in 1834, and proved a complete success. The art union of London soon followed that of Edinburgh.

Arta, är'ta, the name of a gulf, town, and river. The gulf (ancient *Ambracius Sinus*), an arm of the Ionian Sea, between Greece and Albania, is about 20 miles long by 10 miles broad. Near its entrance the battle of Actium was fought. The town, called also Narda (the ancient *Ambracia*), about six miles north of the gulf, stands on the river, which is here about 200 yards wide, and begins to be navigable. It carries on a considerable trade in wine, oranges, and tobacco. Pop. (1896) 7,582.

Ar'taba'nus IV., the last of the Parthian monarchs, who 217 A.D., escaping with great difficulty from a perfidious massacre begun by the Romans under Caracalla, mustered an army, and engaged his foes in a battle which lasted for two days. Peace was then concluded, but Artabanus afterward incited his subjects to revolt, and in a battle, in 226, was taken and put to death.

Ar'taba'zus, the name of several distinguished Persians under the dynasty of the Achæmenidæ. When Xerxes advanced against Greece, an Artabazus led the Parthians and Chorasmians. Another Artabazus was general under the Persian king, Artaxerxes II., and afterward revolted against Artaxerxes III. He was forgiven through the exertions of his brother-in-law, Mentor, a favorite and staunch supporter of the next king, Darius, whom Artabazus faithfully attended after the battle of Arbela. Alexander rewarded his fidelity by appointing him satrap of Bactria.

Artagnan d', där'ta-nyän', the hero of Dumas' ‹Trois Mousquetaires,› Vingt ans après, and Le Vicomte de Bragelonne.› He is a Gascon adventurer, very popular among heroes of romance. There was, however, a Count d'Artagnan (b. about 1612; d. 1673), who was an officer of musketeers, and fell in the siege of Maestricht.

Artasires, (är'ta-väs'dēz) the last Arsacid monarch of Armenia. He was placed on the throne by Bahram V. of Persia, who afterward deposed him and annexed his dominions to Persia, under the name of Persarmenia, 248 B.C.

Artavasdes (är'ta-väs'dēz) **I.,** a king of Armenia, who succeeded his father Tigranes. He joined the Roman forces commanded by Crassus, but deserting to the enemy, caused the defeat of the Romans, and the death of Crassus. He similarly betrayed Mark Antony when engaged against the Medes; but afterward falling into Antony's power, was taken with his wife and children to Alexandria, where they were dragged at the victor's chariot wheels in golden chains. After the battle of Actium, Cleopatra caused his head to be struck off and sent to the King of Media.

Artax'ata, the name of the ancient capital of Armenia, the refuge of Hannibal when forsaken by Antiochus. Its ruins are now known as Ardashir.

Artaxerxes, är'täks-ėrks'ēz, the name of several Persian kings: (1) ARTAXERXES I., surnamed LONGIMANUS, because his right hand was longer than his left, the second son of Xerxes, escaped from Artabanus and the other conspirators who had murdered his father and elder brother Darius, and in 465 B.C. ascended the throne. He conquered the rebellious Egyptians, terminated the war with Athens by granting freedom to the Greek cities of Asia, governed his subjects in peace, and died 425 B.C. (2) ARTAXERXES II., surnamed MNEMON, from his strong memory, succeeded his father, Darius II., in the year 405 B.C. After vanquishing his brother Cyrus he made war on the Spartans, and forced them to abandon the Greek cities and islands of Asia to the Persians. He favored the Athenians, and endeavored to foment dissensions among the Greeks. His last days were embittered by the unnatural conduct of his son Ochus, who, to secure the crown to himself, caused the destruction of two of his brothers. On the death of Artaxerxes Mnemon, 359 B.C., Ochus ascended the throne under the name of (3) ARTAXERXES OCHUS. After having subdued the Phœnicians and Egyptians, and displayed great cruelty in both Egypt and Phœnicia, he was poisoned in 339 by his general, Bagoas. (4) ARTAXERXES BEBEGAN was the first king of Persia of the race of Sassanides. He was a shepherd's son; but his grandfather, by the mother's side, being governor of a province, he was sent to the court of King Ardavan. On his grandfather's death, Artaxerxes, exciting the people to revolt, defeated and slew Ardavan and his son, and assumed the title of King of Kings. He made vast conquests, and wisely administered the affairs of his kingdom.

Artedi, är-tā'de, **Peter,** an eminent Swedish naturalist: b. Anund, 22 Feb. 1705; d. Amsterdam, Holland, 27 Sept. 1735. He went in 1724 to Upsala, and turning his attention to natural history, soon rose to considerable eminence, particularly in the department of ichthyology, the classification of which he reformed upon philosophical principles. This arrangement added greatly to his reputation as a naturalist at the time, and afterward became popular over Europe. In 1728 his celebrated countryman, Linnæus, arrived in Upsala, and a lasting friendship was formed between the two men. In 1732 both left Upsala — Artedi for England, in pursuit of his favorite study; and Linnæus for Lapland, to examine its natural productions; but before parting they reciprocally bequeathed to each other their manuscripts and books upon the event of death. According to agreement his manuscripts came into the hands of Linnæus, and his ‹Bibliotheca Ichthyologica› and ‹Philosophia Ichthyologica,› together with a life of

the author, were published at Leyden in the year 1738. Linnæus named a genus of umbelliferous plants Artedia, in memory of his friend.

Arte'mia. See Brine-Shrimp.

Ar'temido'rus, a Greek geographer: b. in Ephesus, who flourished about 100 B.C. His 'Geographoumena' in clever books was an exhaustive work on the various features, geographical, physical, historical, and political, of the larger part of the then known world, founded on the writer's own investigations and the works of preceding writers. Only fragments of his work are extant.

Ar'temis, a Greek goddess, identified with the Roman Diana. She was the daughter of Zeus (Jupiter) and Leto or Latona, and was the twin sister of Apollo, born in the island of Delos. She is variously represented as a huntress, with bow and arrows; as a goddess of the nymphs, in a chariot drawn by four stags; and as the moon goddess, with the crescent above her forehead. She was a maiden divinity, demanding the strictest chastity from her worshippers, and is represented as having changed Actæon into a stag, and caused him to be torn in pieces by his own dogs, because he had secretly watched her as she was bathing. The Artemisia was a festival celebrated in her honor at Delphi. The famous temple of Artemis at Ephesus was considered one of the wonders of the world, but the goddess worshipped there was very different from the huntress goddess of Greece, being of Eastern origin, and regarded as the symbol of fruitful nature.

Artemisia I., är'te-mĭzh'i-a, or mĭsh-ĭ-ă, a queen of Caria, who lived in the 5th century B.C., and assisted Xerxes in person against the Greeks, and behaved with such valor that the Athenians offered a reward for her capture, and the Spartans erected a statue to her.

Artemisia II., a queen of Caria, who flourished about 350 B.C. She was the sister and wife of Mausolus, whose death she lamented deeply, and to whom she erected, in her capital, Halicarnassus, a monument reckoned among the seven wonders of the world. The principal architects of Greece labored on it. Bryaxis, Scopas, Leochares, and Timotheus made the decorations on the four sides of the edifice; Pythes, the chariot drawn by four horses, which adorned the conical top. Vitruvius thought that Praxiteles was also employed on it. After the death of Artemisia the artists finished it without compensation, that they might not be deprived of the honor of their labor. It was an oblong square, 411 feet in compass, and 130 feet high. The principal side was adorned with 36 columns, and 24 steps led to the entrance.

Artemisia, a genus of aromatic, acrid, and bitter flavored herbs and shrubs of the natural order *Compositæ,* mostly natives of the northern hemisphere and especially abundant in arid regions. The species are characterized by alternate often deeply-lobed or divided leaves, and numerous small and generally inconspicuous heads of yellow or whitish florets. The cultivated species, of which there are many, are readily propagated by division and succeed even on poor dry soils. *A. dracunculus,* tarragon or estragon, is a Siberian perennial, long and widely cultivated in Europe, but little in America, for its leaves, which are used to season dressings, pickles, and other culinary preparations. (See Tarragon.) *A. absinthium,* wormwood, a native of Europe and Asia, is a spreading and branching perennial herb, 2 to 4 feet tall, with its two- or three-parted silky-downy leaves, and its flower-heads in axillary panicles. It is widely grown in Europe for the manufacture of absinthe (q.v.). *A. abrotanum,* southernwood, old man, is a shrubby species, 3 to 4 feet tall, a native of middle Asia and southern Europe, and is often grown for its pleasant-smelling foliage, which is used among clothing as a moth repellant, and in parts of Europe in the manufacture of some kinds of beer. *A. pontica,* Roman wormwood, another European species, resembles *A. absinthium* in properties and is similarly used. *A. vulgaris,* mugwort, is a native of Europe and northern North America, grown for its pleasant-smelling ornamental foliage, which in some varieties is golden or variegated. Its young shoots and leaves are used in German cookery, and like *A. absinthium,* in domestic medicine. *A. stelleriana,* old woman, a native of northeastern Asia and common on the Massachusetts coast, is a useful border plant on account of the whiteness of its foliage. *A. arbuscula,* a species seldom more than one foot tall, and *A. tridentata,* which though usually low growing, occasionally reaches a height of twelve feet, are representative of the many species known as sage brush (q.v.) in the arid districts of the western United States, where they furnish valuable forage for cattle and especially sheep. *A. mantima* and several other species are grown for their flower heads, which are used in medicine as a vermifuge and sold under the name of worm seed or as santonine, the colorless crystalline active principle. *A. moxa, A. chinensis,* and other species furnish moxa, a cottony material obtained from the leaves which are covered with down, used by the Chinese for cauterizing. Numerous other species are employed in the manufacture of absinthe, for culinary, ornamental, and medicinal purposes in various parts of the world. For physical action and toxicology, see Absinthe.

Artemisium, är-te-mĭsh-ĭ-um, a promontory in Eubœa, an island of the Ægean, near which a great naval battle between the Greeks and Persians was fought, 480 B.C. It was named from a temple to Artemis situated here.

Ar'temus Ward. See Browne, Charles Farrar.

Arte'rial Pressure. See Blood Pressure.

Ar'teries, the vessels in the human body that carry arterial, or oxygenated blood away from the heart. The old name, signifying carriers of air, is retained, although the ancient belief has been laid aside. The arteries spring from the heart, as the aorta (q.v.) and by the branching and division of the main branches of this large arterial trunk, are distributed in successively finer branches to all parts of the human body. The blood supply for the head is mainly derived from the carotid arteries, the superficial, or external carotid, supplying the outer structures, and the deep or internal carotid that gives nourishment to the brain and deeper lying parts. There are numerous anastomoses between the branches of the carotid arteries. The main sup-

ply of the arm has been described under the head aorta (q.v.), as well as the branches that supply the viscera and the lower limbs. Arteries become smaller and smaller as they approach the periphery of any organ and are finally converted into capillaries which anastomose with the capillaries of the veins; these carry the blood back to the heart and thus the circle is completed. The minute structure of the arteries is well adapted to the varying functions that these vessels perform. In every large and medium-sized artery, three distinct layers or coats may be distinguished under the miscroscope. The inner coat, or the *tunica intima,* is thin and smooth, and consists of an inner layer of flat plate-like endothelial cells that are continuous throughout the entire system of blood vessels. This endothelial layer by its smoothness reduces friction of the flowing blood to a minimum. Surrounding it are two layers of fibrous elastic tissues. The middle coat of the arteries is the *tunica media* and is composed mostly of smooth muscle fibres, with some fibrous tissue. These muscle fibres are arranged in a circular manner about the arteries. The outer coat, or the *tunica adventitia,* is made up of white fibrous tissue. Thus the arteries have elastic and fibrous tissues in each coat. The outer layer is extremely tough and thus strengthens and protects; the middle layer by means of its elasticity permits the artery to return to its average diameter after it has been dilated or contracted by the muscular layer. In the larger arteries the yellow fibrous tissue predominates, while in the smaller arteries there is a relatively larger amount of muscle fibre. The large arteries are thus more elastic and less contractile, while for the smaller arteries the reverse is true. The muscle fibres are under the control of the sympathetic nervous system nerve fibres. In the capillaries the artery is reduced to its single endothelial layer, and has neither elastic fibres nor muscle fibres.

Arteries, Diseases of. The arteries are subject to a number of diseases which may be classed as (1) due to infectious micro-organisms, (2) degenerations with increase of connective tissue, (3) aneurisms. Of the acute infectious diseases, tuberculosis and syphilis, particularly the latter, are important. Syphilis is one of the most important causes of arterial degeneration. *Acute arteritis* is a definite disease, although the great pathologist, Virchow, taught that it was a secondary affection. Recent bacteriological studies, however, have shown that bacterial infection of the arterial walls is a fundamental and important process. It is frequently the cause of an arterial thrombus and often develops into a true arteriosclerosis. Under the general head arteriosclerosis is classed a diffuse or circumscribed thickening of the arterial walls, especially of the *tunica intima,* secondary to inflammatory or degenerative changes in the *tunica media.* When occurring in the large arteries, the term *atheroma* is used. Arteriosclerosis is sometimes found in the young, but is usually a disease of later life. Among the causes favoring its development are: (1) changes in the composition of the blood, such as toxins from bacterial infections (syphilis, rheumatism), metallic poisons, alcohol, and the disturbed metabolism of gout, Bright's disease, etc., and (2) changes in the tension of the blood vessels. These occur as a result of excessive and prolonged muscular exertion and intense emotional activity. Arteriosclerosis may be circumscribed or diffuse. It may show irregular plaques of a transparent or gelatinous character which at a later period become hard and firm, or even calcified with the formation of brittle or pipe stem arteries. Sometimes the arteries undergo a fatty degeneration. There is a proliferation of the connective tissue and a degeneration of the elastic tissue. The arteries thus become less responsive to control and so interfere with the nervous impulses. In the diffuse form the proliferation and degeneration is more uniform. Arteriosclerosis is one of the most important of all diseases since by its interference with the proper blood supply of an organ, it may occasion disease in that organ. In pronounced generalized arteriosclerosis all of the organs of the body suffer. Arteriosclerosis is one of the most important elements in the production of cerebral hemorrhage, one of the forms of apoplexy. Aneurisms have already been considered under that heading.

Arte'riosclero'sis. See ARTERIES, DISEASES OF.

Artesian (är-tē'zhăn) **Wells,** borings of considerable depth which tap a subterranean stream or sheet of water. The name is derived from artois (Latin *artesium*), a province in France where the first deep borings in Europe were made. Strictly speaking the term artesian is applicable only to such wells as discharge water at the surface under natural conditions (that is, self-flowing wells), but in America the term is commonly applied to any wells of more than ordinary depth. As the latter type of wells does not possess any features of special interest the term will here be used in its limited sense. The conditions which determine the presence of artesian water in a region relate to the geological structure of the underlying strata. It is essential in the first place that a pervious stratum enclosed above and below by impervious layers be present. The pervious bed, usually sandstone or sand, serves as a reservoir for the accumulation of water, while the impervious beds prevent this water from escaping either upward or downward. The second requisite is that the strata have a gentle pitch toward the site of the well and that they outcrop at some place above the mouth. The distance of the outcropping edges, which receive the water supply from rains, is sometimes very great, and is immaterial if the enclosing beds are perfectly impervious, except as it modifies the resistance offered to the passage of the water. Owing to this friction the water column of the well never reaches the level of the outcropping source. The conditions for artesian water are particularly favorable when the strata are arranged in the form of a geological basin dipping in all directions toward the well, as there then is no opportunity for the water to escape at a lower level. From these considerations it is evident that the discharge from an artesian well depends upon the rainfall of the region and upon the area of the exposed porous stratum. At first the discharge is usually very abundant owing to the long accumulation, and unless this drain is constantly supplied the flow will gradually decrease until a balance is established. When several wells are bored in the same vicinity, the flow from each may be diminished, but the total discharge will increase until the limit of supply is reached. This is

well illustrated in the wells bored in the London basin which in 1838 gave a total daily supply of 6,000,000 gallons; in 1851 with a larger number of borings the supply was about doubled, while the force had diminished very markedly. Artesian water is valuable not only for domestic use, for which it is usually adapted by its purity, but it is also extensively employed in the irrigation of arid regions. Some parts of the Sahara Desert have been reclaimed by making use of the subterranean stores of water, and recent investigations have shown that there are many areas which may yet be brought under cultivation. It is, however, in the United States that irrigation by artesian waters has reached its greatest development. Special surveys of the Great Plains region have been undertaken by the United States Geological Survey for the purpose of defining the areas where successful borings may be made, and artesian wells are now largely employed for irrigation in Kansas, Iowa, Colorado, Montana, and Texas. The supply is drawn mostly from the Cretaceous sandstone, which is reached at a depth varying from less than 100 to more than 1,500 feet. When the flow of water is sufficiently strong it may be utilized for power purposes as is done in some parts of Europe. In Würtemberg a supply of warm water is applied to the heating of buildings.

The depth at which artesian water may be found depends entirely upon local conditions. In the Paris basin the water-bearing stratum is usually encountered at a depth exceeding 1,500 feet. The famous well at Grenelle, near Paris, was begun in 1833, and operations were continued until 1841 when at a depth of 1,797 feet the water poured out with great force at the rate of 500,000 gallons per day. Another well was sunk near by at Passy, which yielded 5,600,000 gallons daily, the water rising to a height of 54 feet above the mouth. This well was 1,923 feet deep and had the unusual diameter of 2 feet 4 inches. A well at Kissingen, Bavaria, furnishes a supply of saline water from a depth of 1,878 feet. The deepest well in the world is at Schladenbach, near Leipsic, 5,735 feet. In the United States there are many notable examples of artesian wells. The first boring of great depth was made at St. Louis in 1849–54; a flow of 75 gallons per minute was obtained from a depth of 2,200 feet, but the water was so heavily charged with sulphuretted hydrogen and mineral matter as to be unfit for domestic use. Another boring was subsequently made to a depth of 3,843 feet. A well at Louisville, Ky., is 2,086 feet deep and yields 330,000 gallons per day. Among other noteworthy wells are the following: Columbus, O. (2,775 feet); Galveston, Tex. (3,071 feet); Charleston, S. C. (1,250 feet); Pittsburg, Pa. (4,625 feet); and Chicago (710 feet). A great many wells have been bored in recent years within the Atlantic Coastal Plain, especially in New Jersey, and many cities have thus obtained supplies of pure water. The cost of sinking artesian wells varies with the depth and the character of the strata encountered. Up to 500 feet the cost commonly ranges from $1.50 to $3.00 per foot, but below this limit the cost increases in proportion to the depth. The apparatus used in boring does not differ from that employed in sinking for petroleum. The first artesian borings were probably made by the Chinese. In the upper basin of the Yang-tse-Kiang there are wells 1,500 to 3,000 feet in depth from which brine for salt manufacture is obtained. This industry has been carried on since a very early period and is an illustration of the comparatively advanced state of progress attained by this people long before the western nations had developed the mechanical arts beyond the crude stage. Deep wells have been found also in Egypt which are thought to have been the work of the ancient Egyptians. A well bored in the year 1126 at Lillers, department of Pas-de-Calais, France, is still flowing.

Arteveld, är'tĕ-vĕl'dĕ, or **Artevelde**, the name of two men distinguished in the history of the Netherlands. (1) Jacob van, a brewer of Ghent, b. about 1290; d. 17 July 1345. He was selected by his fellow townsmen to lead them in their struggles against Count Louis of Flanders. In 1338 he was appointed captain of the forces of Ghent, and for several years exercised a sort of sovereign power. A proposal to make the Black Prince, son of Edward III. of England, governor of Flanders, led to an insurrection, in which Arteveld lost his life. (2) Philip van, son of Jacob: b. 1340; d. 27 Nov. 1382. At the head of the forces of Ghent he gained a great victory over the Count of Flanders, Louis II., and for a time assumed the state of a sovereign prince. His reign proved short-lived. The Count of Flanders returned with a large French force, fully disciplined and skilfully commanded. Arteveld was rash enough to meet them in the open field at Roosebeke, between Courtrai and Ghent, in 1382, and fell with 25,000 Flemings. See Ashley, 'James and Philip van Artavelde' (1883); Hutton, 'James van Artavelde' (1882).

Artevelde, Philip van, the title of a tragedy by Sir Henry Taylor, published in 1834. It is one of the best of modern English tragedies by an author distinguished for his protest, in the spirit of Wordsworth, against the extreme sentimentalism of Byron. In this play with admirable power he brings back the stress and storm of 14th century life. The father of Philip, the great Jacob van Artevelde, an immensely rich brewer, eloquent and energetic, had played a great part as popular leader at Ghent, 1335–45; and it fell to his son to figure similarly in 1381, but to be slain in a great defeat of the forces of Ghent the next year. Taylor's tragedy recalls the events of these two years.

Art'ful Dodg'er, The, the nickname of John Daukins, a young pickpocket in Dickens' 'Oliver Twist.'

Arthralgia (Neo.-Lat. from Gr. ἄρθρον, joint, + ἄλγος, pain), pain in a joint; used more specifically of neuralgia in a joint. It is synonymous with arthrodynia.

Arthri'tis, an acute or chronic inflammation of the joints, usually due to bacterial infection. Such infection may follow a wound, a perforating injury, an operative incision, or the micro-organisms may come to the joint through the blood stream, as in rheumatism, gonorrhœa, typhoid, or pyemia. In some cases of arthritis the causes seem to be resident in defective metabolism — gout is an illustration of this type of arthritis. In acute cases there are pain, swelling, heat, and occasionally suppuration. In the chronic forms the main symptoms are pain and

stiffness. The treatment should include rest, counter-irritation, and, in the suppurative cases, prompt surgical attention. In the more chronic cases counter-irritation, dry, hot air, static electricity, and potassium iodid are of service. See ANTHRITIS DEFORMANS; GOUT; JOINT; RHEUMATISM.

Arthritis Deformans (rheumatoid arthritis, or osteo-arthritis), a chronic progressive disease of the joints, chiefly affecting the articular cartilages, bones, and synovial membranes, and producing loss of function and great deformity from ossification of some parts of the joint and atrophy of others. Its origin is not definitely known. Though it is sometimes spoken of as rheumatic gout, it is believed to have nothing in common with rheumatism or gout, but may co-exist with either.

It is very rare in children, occurs occasionally in old age, is more common between 25 and 50, and in females than in males. It most often appears after the menopause, though it may occur earlier, as when following parturition. It is doubtful whether the disease is hereditary, although several cases may occur in one family. Exposure to inclement weather, dietetic errors, injuries, etc., have less causative influence than in gout or rheumatism, but poor food, debility, anæmia, and cold and damp increase the severity of the disease. Mental strain precedes many cases and adds very much to the severity of the disease.

There are two theories as to the immediate cause of the affection. The first, the nervous or neuropathic theory, is based upon the symmetrical distribution of the joint-lesions, the trophic changes in the skin, nails, etc., the frequent pre-existing mental disturbances, shock, grief, worry, and the like, the disproportionate muscular atrophy, and the similarity of the lesions to those of locomotor ataxia and other affections of the spinal cord. The second or infectious theory is derived from the facts that micro-organisms have been found in the fluids and tissues of the joints, that the disease sometimes begins with an acute onset, as do many of the infectious diseases, and that enlargement of the spleen and lymph-glands is found in some cases. It is difficult to say which tissue is primarily at fault, but sooner or later nearly all are involved. The synovial membrane inflames, and papillary outgrowths and cartilaginous nodules form upon it. These last may undergo fatty degeneration, or they may ossify. They may slip into the joint-cavity. If serous effusion occurs it is absorbed early in the disease. The cartilages lose their cells, become fibrillated and soft, and are removed by friction and absorption. The ends of the bones (the interarticular cartilages being absorbed) by friction become smooth, rounded, and shiny, like polished ivory (eburnated). The eburnated surfaces, by attrition, become grooved, and minute perforations of the Haversian canals result. Deposits of new bone form around the margins of the joints, and may be often felt externally. The muscles atrophy and are of a brownish color. Fibrous adhesions and bony anchylosis occur. Some of the small joints of the fingers, for example, may move a little, but the knees, etc., may be interlocked, by reason of the rims of bony material deposited. Dislocation or subluxation may result. The periosteum along the shafts of the bones may thicken or ossify in nodules.

The acute form of the general or multiple progressive type is rare after 40. Smaller joints become simultaneously painful, tender, and swollen, but not red as in rheumatism; there is no migration from joint to joint, the affected joints are inflamed, while others are becoming diseased. Patients are anæmic, mentally depressed, and complain of headache and malaise. Fever seldom goes above 102°. Temporary improvement occurs, but the disease advances. The chronic form of this type is insidious and more common. One joint (of finger or toe) is involved; the disease affects the corresponding joint, and then other joints; pain may be mild or very severe; there are delusive intervals while the disease marches on. After months, or it may be years, all or nearly all of the joints are thickened, rigid, and distorted. The hands are bent toward the ulnar side, fingers strongly flexed, nails in the palms of the hands. The thumbs, though drawn in, may be used. The knees are generally crossed. The general health through it all may be fair, as visceral lesions are uncommon.

In the monarticular or localized type, the disease is usually confined to one or two of the larger joints, occurs mostly in men, and after 50. The knee, shoulder, elbow, or hip is generally affected, but the vertebræ may be, the entire spinal column becoming rigid. Motion of affected joints often produces a creaking or grating sound. The pathological appearances are similar to those of the general type of the disease, but joint-injuries are more often an exciting cause. The joint becomes stiff, sore, and painful, and there is absorption of the ends of the bones, dislocation, and deformity.

Heberden's nodes or nodosities, described by him in 1805, are small exostoses («small hard knobs»), seldom larger than peas, which form on either side of the distal joints of fingers. They may be present in either type of the disease, at first are tender and swollen, but later on apparently cause little discomfort. Sometimes the bone-enlargement surrounds the joint.

Arthritis deformans in children, although not frequent, is more acute, and is more influenced by poor food, cold and damp, etc. There is fever, sometimes a chill. The swelling, stiffness, and tenderness seem to be more in the soft parts than in harder tissues. The fingers are flexed and overlapped, the feet are strongly extended, and the joints are rigid.

The diagnosis of arthritis deformans must be made from subacute and chronic rheumatism, gonorrhœal rheumatism, gout, progressive muscular atrophy, Charcot's disease, etc. Recovery is impossible, but the disease is not directly dangerous to life. Treatment for relief is hygienic and dietetic, a warm, dry, equable climate, dry, healthful quarters, change of scene, freedom from anxiety, shock, etc., woolen underclothes, flannel nightgowns or pajamas, and ample diet. Malt extracts, iron, and cod-liver oil are of service. Locally there should be application of massage, friction, electricity, douching, hot air in so-called hot-box, guiacol and glycerine in equal parts, or belladonna ointment, cotton, and oil-silk. Residence at one of the spas, with appropriate care and treatment, will relieve suffering and prolong life. See ARTHRITIS; GOUT; JOINT; RHEUMATISM.

Arthrocace (Neo.-Lat. from Gk. ἄρθρον, joint + κακή, evil), a disease of the joints in which the bone is disintegrated and carried away piecemeal. See CARIES.

Arthro'dia. See JOINT.

Arthrodynia (Neo.-Lat. from Gk. ἄρθρον, joint + ὀδύνη, pain), pain in a joint; practically synonymous with arthralgia.

Arthrogastra (Neo.-Lat. from Gk. ἄρθρον, joint + γαστήρ, abdomen), a division of the insect class Arachnida (q.v.), having the abdomen annulated, and including the scorpions (see SCORPION), etc.

Arthromere (Gk. ἄρθρον, joint + μέρος, part), one of the series of segments of which arthropoda (q.v.) are composed.

Arthropathia Tabidorum, a disease of the joints in connection with spinal disease (*tabes dorsalis*), very similar to *arthritis deformans* (q.v.). The destruction of the ends of the bones in the joint concerned takes place with great rapidity and painlessly; there is no fever nor appearance of inflammation, even when the bones are fractured.

Arthrophragm (Gk. ἄρθρον, joint + φράγμα, fence), a partition between certain articulations, as, for example, in the crayfish (q.v.).

Arthropleure (Neo.-Lat. *Arthropleura*, from Gk. ἄρθρον, joint + πλευρά, side), the lateral portions of the arthroderm, or crust, of articulated animals. See ARTICULATA.

Arthrop'oda, a phylum comprising those articulated animals which have jointed appendages, such as antennæ, jaws, maxillæ (or accessory jaws), palpi, and legs, arranged in pairs, the two halves of the body thus being more markedly symmetrical than in the lower animals. It is by far the most numerous in species of any in the animal kingdom, the insects alone probably numbering upward of a million species; other representative or typical forms are the trilobites, king crabs, scorpions, spiders, and myriopods. The skin is usually hardened by the deposition of salts (carbonate and phosphate of lime), and of a peculiar organic substance called chitine. The segments (somites or arthromeres) composing the body are usually limited in number, 20 (or 21) in the crustaceans and insects; while each arthromere is primarily divided into an upper (tergum), lower (sternum), and lateral portion (pleurum). These divisions, however, cannot be traced in the head of either the crustaceans or the insects. Moreover, the head is well marked, with one or two pairs of feelers or antennæ, and from two to four pairs of biting mouth-parts or jaws, and two compound eyes; besides the compound eyes there are simple eyes in the insects. The germ is three-layered, and there is usually in the more specialized forms a well-marked metamorphosis. The *Arthropoda* are most nearly related to the worms, certain annelides, with their soft-jointed appendages (tentacles as well as lateral cirri) and more or less definite head, anticipating or foreshadowing the arthropods. On the other hand, certain low parasitic arthropods, as linguatula, have been mistaken for genuine parasitic worms.

Segmentation of the Body.— The segments (somites, metameres) are merely thickenings of the skin connected by a thin intersegmental membrane, so that the segments can telescope into each other, or extend, thus lending the greatest freedom of motion to the trunk as well as to the appendages; otherwise a rigid chitinous skin would not permit of any movement. As in the annelid worms, this segmentation of the integument is correlated with the serial repetition of the ganglia of the nervous system, of the ostia of the dorsal vessel, the primitive disposition of the segmental and reproductive organs, of the soft, muscular dissepiments which correspond to the suture between the segments, and with the metameric arrangement of the muscles controlling the movements of the segments on each other; and this internal segmentation or metamerism is indicated very early in embryonic life by the mesoblastic somites.

While we look upon the dermal tube of worms as a single but flexible lever, the body of the arthropods, as Graber states, is a linear system of stiff levers. We have here a series of stiff, solid rings, or hoops, united by the intersegmental membrane into a whole. When the muscles extending from one ring to the next behind contract, and so on through the entire series, the rings approximate each other.

The origin of the joints or segments in the limbs of arthropods was probably due to the mechanical strains to which what were at first soft fleshy outgrowths along the sides of the body became subjected. Indeed, certain annelid worms of the family *Syllidæ* have segmented tentacles and parapodia, as in Dujardinia. We do not know enough about the habits of these worms to understand how this metamerism may have arisen, but it is possibly due to the act of pushing or repeated efforts to support the body while creeping over the bottom among broken shells, over coarse gravel, or among sea-weeds. It is obvious, however, that the jointed structure of the limbs of arthropods, if we are to attempt any explanation at all, was primarily due mainly to lateral strains and impacts resulting from the primitive endeavors of the ancestral arthropods to raise and to support the body while thus raised, and then to push or drag it forward by means of the soft, partially jointed, lateral limbs which were armed with bristles, hooks, or finally claws. By adaptation, or as the result of parasitism and consequent lack of active motion, the original number of segments may by disuse be diminished. Thus in adult wasps and bees, the last three or four abdominal segments may be nearly lost, though the larval number is ten. During metamorphosis the body is made over, and the number, shape, and structure of the segments are greatly modified.

History and Present Classification.— The group or sub-kingdom (phylum) of *Arthropoda* was founded in 1848 by Siebold. It has been supposed until recently to be a natural group. In 1893 Kingsley, and also Kennel, first suggested doubts as to the homogeneity of the group, and in the same year Packard published the view that there are four independent lines of development in the *Arthropoda*, and in 1894 Kingsley divided the group into three subphyla, Laurie and Pocock also considering that the group is polyphyletic. In 1898 Packard stated: "It is becoming evident, however, that there was no common ancestor of the *Arthropoda* as a whole, and that the group is a polyphyletic one.

Hence, though a convenient group, it is a somewhat artificial one, and may eventually be dismembered into at least three or four phyla or branches.»

The four phyla as afterward proposed by Packard are, beginning with the most primitive: (1) *Palæostraca,* embracing the classes of *Trilobita;* (2) *Merostomata* (*Limulus*), and *Arachnida;* (3) *Pancarida* (*Crustacea*); (4) *Prosogoneata,* including three classes: *Pauropoda, Diplopoda,* and *Lymphyla* (*Scolopendrella*); and (5) *Entomoptera,* comprising the *Chilopoda* and *Insecta;* the great majority of the group being winged insects. Each of these phyla represent independent lines of development, judging by their structure and what we know of their development, and have no genetic connection beyond the theory that they each have descended from one or more annelid worms.

A. S. PACKARD,
Late Prof. Zoology, Brown University.

Arthrostraca, crustacea of the sub-class *Malacostraca* in which the first, sometimes the second thoracic segment is fused with the head and bears maxillipedes; the remaining seven being free and bearing legs. The eyes are usually sessile. The group is divided into the *Amphipoda* (q.v.) and *Isopoda* (q.v.). Common examples are pill-bug, wood-louse, etc.

Ar'thur, king of the Silures in the 6th century, an ancient British hero, whose story has been the theme of much romantic fiction. He is said to have been the son of Uthyr, chief commander of the Britons, and to have been born about 501. In 516 he succeeded his father in the office of general, and performed those heroic deeds against the Saxons, Scots, and Picts which have made him so celebrated. He married the celebrated Guinevere belonging to the family of the dukes of Cornwall; established the famous order of the Round Table; and reigned, surrounded by a splendid court, 12 years in peace. After this, he is reported to have conquered Denmark, Norway, and France, slain the giants of Spain, and journeyed to Rome. From thence he is said to have hastened home on account of the faithlessness of his wife, and Modred, his nephew, who carried on an adulterous intercourse, and stirred up his subjects to rebellion; to have subdued the rebels, but to have died in consequence of his wounds, in 542, on the island of Avalon, where it is pretended that his grave was found in the reign of Henry II. The story of Arthur is supposed to have some foundation in fact, and it is generally believed that he was one of the last great Celtic chiefs who led his countrymen from the west to resist the settlement of the Saxons in southern Britain. But many authorities regard him as a leader of the Cymry of Cumbria and Strath-Clyde against the Anglo-Saxon invaders of the east coast and the Picts and Scots north of the Forth and the Clyde. In our own day the interest of the old legends has been revived by the works of Lytton and especially Tennyson. See Skene, 'Four Ancient Books of Wales' (1868); Stuart-Glennie, 'Journey through Arthurian Scotland' (1867); and 'Arthurian Localities' (1869); Rhys, 'Studies in the Arthurian Legend' (1891); Sommer, 'Morte d'Arthur' (3 vols. 1889–91); Brown, 'Twain: A Study in the Origin of Arthurian Romance' (1902). See ARTHURIAN LEGENDS.

Ar'thur, Prince. See DUKE OF CONNAUGHT.

Ar'thur, duke of Brittany, the grandson of King Henry II. of England: b. 1187; d. 1203. On the death in 1199 of his uncle, Richard I., who had declared the boy his heir, Arthur was proclaimed king of England by the nobles of Anjou, Touraine, and Maine, while the English lords decided in John's favor. King Philip of France supported the claims of Arthur, but a peace being presently concluded between John and Philip, Arthur came later into the hands of his uncle, King John, and soon mysteriously disappeared. According to general belief Arthur was murdered by command of his uncle. The story of Arthur forms a portion of Shakespeare's 'King John.' See JOHN.

Arthur, Chester Alan, the 21st President of the United States: b. Fairfield, Vt., 5 Oct. 1830; d. New York, 18 Nov. 1886. He graduated from Union College at 18, was principal of an academy at North Pownal, Vt., and in 1853 began the practice of law in New York, where he argued several important legal cases in behalf of the colored people. Through these and other cases he became noted in his profession, and he was also prominent as a Republican politician. In April 1861 Gov. E. D. Morgan made him acting quartermaster-general, and later he was made full quartermaster-general. For the next decade he was a successful and widely known practising lawyer, and a leading Republican politician of New York, chairman of the Grant Club in 1868, and of the executive committee of the Republican State committee in 1869. He was appointed by President Grant, 20 Nov. 1871 to the highest office in the State patronage, the collectorship of the port of New York, which he held till 11 July 1878. His business conduct of the office was not impeached, and he was retained by President Hayes for over a year after his accession; but he was first of all a political manager, in open hostility to civil service reform. As a matter of actual practice and not theory, however, Mr. Arthur produced figures to show that the annual percentage of removals under him for all causes had been only 2¾ per cent, as against an annual average of 24 per cent since 1857. In 1880 he was nominated for the vice-presidency, chiefly to conciliate the Grant section of the Republicans, sore at the defeat of the third-term project, and was elected with Garfield. In place of the customary dignified nullity of his office, he remained an active party leader in the patronage contest of his State, between the «Stalwarts» or Grant section led by Roscoe Conkling (q.v.), and of which Mr. Arthur was chief lieutenant, and the «Half-Breeds» or more independent wing which Garfield was trying to build up. Conkling soon resigned his seat in the Senate, declaring that Garfield had broken his promises to him, and the Garfield party for the time was triumphant; but the assassination of Garfield, shortly after, reversed the situation. The open lamentations of the press at the prospect of the accession of so convinced a spoilsman as himself deeply hurt Mr. Arthur, who felt that he was misjudged, and determined on the most admirable revenge, that of disappointing their prophecies of evil. He did so; not only was his term of office measurably free from the dominance of patronage, but he extended the civil service rules and kept faith with them. In other respects his ad-

CHESTER ALAN ARTHUR.

21ST PRESIDENT OF THE UNITED STATES.

ministration was so excellent that the leading Independents had announced their intention of supporting him for President if nominated in 1884. Its most notable incident was the appointment of a commission to revise the tariff, which, though composed of strong Protectionists, reported that the tariff should be reduced 20 per cent all around, a recommendation unheeded by Congress. Several commercial treaties were passed, however. He vetoed a Chinese immigration bill as inconsistent with treaty obligations; favored the stringent laws passed against polygamy, appointing a Utah commission to supervise their enforcement; managed Indian affairs wisely, promoting Indian education and the breaking up of the tribal system; extended postal facilities; took measures to increase the navy, improve its discipline and efficiency and provide for coast defense; supported the improvement of Mississippi River navigation, etc. The attempts at remonetizing silver, and at forcibly abrogating the Clayton-Bulwer treaty to build a Nicaragua canal, were in accordance with general party feeling at the time. The lingering scandal of the Star Route frauds, however, injured the party somewhat, and its policy and methods were gravely disapproved of by the Independents; but this was much more than counterbalanced by distrust of the Democratic party for its alliance with the Greenback element. Mr. Arthur's defeat for the nomination was not caused by any demerits of his own, still less by desire to conciliate the Independents, but by the personal ambitions of Republican leaders, which, justly or unjustly, had aroused and exasperated the Republicans of the State of New York, causing the defeat of C. J. Folger for Governor, and resulting in the nomination of Blaine in 1884. Arthur, although a close adherent of Conkling, supported Blaine.

Ar'thur, Joseph Charles, an American botanist: b. Lowville, N. Y., 11 Jan. 1850. He was graduated from Iowa State College in 1872, and subsequently studied at the universities of Johns Hopkins, Harvard, and Bonn, Germany. He was instructor in the universities of Minnesota and Wisconsin; botanist at the Experiment Station, Geneva, N. Y., and is now professor of vegetable physiology and pathology, Purdue University, Lafayette, Ind.

Arthur, Julia, the stage name of Ida Lewis, an American actress: b. Hamilton, Ont., 3 May 1869. She made her professional début at the age of 14 as the Prince of Wales in 'Richard III.' Her first New York success was in 'The Black Masque.' She made her London début February 1895 in Henry Irving's company, playing roles next to Helen Terry, both of whom she accompanied to America in 1896. Since then she has starred chiefly in the United States. She is the wife of B. P. Cheney. See Strang, 'Famous Actresses of the Day in America' (1899).

Arthur, P. M., American locomotive engineer: b. Scotland 1834; d. Winnipeg, Manitoba, 16 July 1903. He came to America in childhood and as a young man was at first a blacksmith's helper in the employ of the New York and Harlem Railroad Company and later an engineer on the New York Central railroad. In 1873 he became the grand chief of the American Brotherhood of Locomotive Engineers, which post he filled at the time of his death.

Ar'thur, Timothy Shay, an American author: b. Newburg, N. Y., 1809; d. Philadelphia, 6 March 1885. In 1852 he founded 'Arthur's Home Magazine.' He was a voluminous writer of moral and domestic tales. His works are over 100 in number, and have had a large sale in England as well as in the United States. His most popular work was the famous 'Ten Nights in a Bar-Room.' Among his other publications were 'Tales for Rich and Poor,' 'Tales of Married Life,' and 'Lights and Shadows.'

Arthu'rian Leg'ends, a series of Celtic romances, which for nearly a thousand years have furnished unlimited literary material, not to English poets alone, but to the poets of all Christendom. These Celtic romances, having their birthplace in Brittany or in Wales, had been growing and changing for some centuries, before the fanciful 'Historia Britonum' of Geoffrey of Monmouth, flushed them with color and filled them with new life. Through his version they soon became a vehicle for the dissemination of Christian doctrine. By the year 1200 they were the common property of Europe, influencing profoundly the literature of the Middle Ages, and becoming the source of a great stream of poetry that has flowed without interruption down to our own day. Sixty years after the 'Historia Britonum' appeared, and when the English poet Layamon wrote his 'Brut' (A.D. 1205), a translation of Wace, as Wace was a translation of Geoffrey, the theme was engrossing the imagination of Europe. It had absorbed into itself the elements of other cycles of legend, which had grown up independently; some of these, in fact, having been at one time of much greater prominence. Finally, so vast and complicated did the body of Arthurian legend become, that summaries of the essential features were attempted. Such a summary was made in French about 1270, by the Italian Rustighello of Pisa; in German, about two centuries later, by Ulrich Füterer; and in English by Sir Thomas Malory in his 'Morte d'Arthur,' finished 'the ix. yere of the reygne of kyng Edward the Fourth," and one of the first books published in England by Caxton, "emprynted and fynysshed in th' abbey Westmestre the last day of July, the yere of our Lord MCCCCLXXXV." It is of interest to note, as an indication of the popularity of the Arthurian legends, that Caxton printed the 'Morte d'Arthur' eight years before he printed any portion of the English Bible, and 53 years before the complete English Bible was in print. It has been said that the original legend absorbed into itself the elements of other cycles of legend. The most important of these was 'The Holy Grail' (q.v.). At once a new spirit breathes in the old legend. In a few years it is become a mystical, symbolical, anagogical tale, inculcating one of the profoundest dogmas of the Holy Catholic Church, a bearer of a Christian doctrine engrossing the thought of the Christian world. In addition to the mystical and religious character of the transformed legend, the spirit of the chivalry of the Middle Ages embodied in it, furnishes an admirable transcript of the social ideal of the times, which thus moulded the older and ruder materials into a more gracious form. The knightly ideals of loyalty, obedience, the redressing of wrongs and especially the veneration of womanhood are distinctively portrayed.

Throughout the Middle Ages it was «our lady,» the Virgin Mother, who embodied and represented to all men and women, from prince to peasant, their ideals of womanhood and ladyhood. And it was the transference of these Christian ethics into the practice of common daily, worldly life, in rude times, which we owe to the institution of chivalry, nowhere better reflected than in the Christianized Arthurian legends. From about 1200, innumerable poets, with diverse tastes, set themselves to produce new versions of the legend, engrafting upon the general theme many diverse stocks. Dante in the ‹Divine Comedy› speaks of Arthur, Guinevere, Tristan, and Launcelot by name, and Boiardo, Ariosto, and Tasso in Italy, Hans Sach in Germany, Spenser, Shakespeare, Milton, and Dryden in England, all made use of the same material.

Of the poets of the present generation, Tennyson has treated the Arthurian poetic heritage as a whole. Phases of the Arthurian theme have been presented also by his contemporaries and successors at home and abroad — by William Wadsworth, Lord Lytton, Robert Stephen Hawker, Matthew Arnold, William Morris, Algernon Charles Swinburne, in England; Edgar Quinet in France; Wilhelm Hertz, L. Schneegans, F. Roeber, in Germany; Richard Hovey in America. There have been many other approved variations on Arthurian themes, such as James Russell Lowell's ‘Vision of Sir Launfal,’ and Richard Wagner's operas, ‘Lohengrin,’ ‘Tristan and Isolde,’ and ‘Parsifal.’ Of still later versions, we may mention the ‘King Arthur’ of J. Comyns Carr, which has been presented on the stage by Sir Henry Irving; and ‘Under King Constantine,’ by Katrina Trask, whose hero is the king whom tradition names as the successor of the heroic Arthur "Imperator Dux Bellorum."

Ar'thur's Seat, a hill overlooking Edinburgh, Scotland, said to have been so called from a tradition that King Arthur surveyed the country from its summit and defeated the Saxons in its neighborhood. It is a steep, and in some places precipitous, rock, exhibiting on the south side a range of perpendicular basaltic columns, called Samson's Ribs. The highest point is 822 feet above sea-level. From hence may be seen a wide expanse of sea, the course of the Forth, the distant Grampians, etc., and a large portion of the most populous and best cultivated part of Scotland, including the picturesque city of Edinburgh and its castle. On the north side are the ruins of a chapel and hermitage, dedicated to St. Anthony, and a fine spring called St. Anton's Well. A carriage road called the Queen's Drive goes round its base.

Ar'tichoke, two species of the natural order *Compositæ.* The true, sometimes called French, artichoke (*Cynnara Carduncculus* — scalymus of some authors), a native of the Mediterranean region, is a coarse, stout, perennial, thistle-like herb, 3 to 5 feet tall, with rather spiny leaves, the lower of which are often 3 feet or more long, and large terminal heads of blue or white flowers. It is cultivated for the edible thickened outer scales and «bottoms» (receptacles) of the flower heads which sometimes exceed 4 inches in diameter without becoming too old for eating raw as salad, pickled, or cooked like cauliflower. Sometimes the young stems and leaves are blanched like cardoon, with which some botanists consider it to be identical. In Europe many varieties are popular; in America the globe variety is planted almost to the exclusion of others, with the result that this variety has almost become united to the name in popular usage. The cultivation of this species in America is confined mostly to the southern States, few gardens in the North being supplied with it. Since the plant is rather tender, winter protection must be given where the ground freezes. If planted in rich soil and set four feet apart the plants will yield two or three crops before a new plantation should be made; if allowed to stand longer the yield gradually diminishes. New plantations are made either with seedling or sucker plants. Most of the artichokes offered in the northern markets of the United States come from France and Louisiana.

The Jerusalem artichoke (*Helianthus tuberosus*), a native of North America, is a perennial sunflower-like herb, 5 to 12 feet tall, with rough leaves 4 to 8 inches long and many yellow terminal flower-heads often 2 to 3 inches in diameter. The edible pear-shaped purplish, red, white, or yellow tubers for which the plant is often cultivated are numerous, seldom more than 3 inches in diameter, rather watery but of pleasant flavor especially when prepared like cauliflower, with a white sauce. Perhaps no vegetable is of easier cultivation. For home use the tubers are generally planted in well-drained soil in some out of the way corner of the garden and allowed to take care of themselves from year to year, the few tubers and pieces of root left after digging sufficing to re-stock the bed. In field culture the methods are like those practised with the potato except that the tubers may be left in the ground over winter and dug when needed. They are not injured by frost if in the soil, but if frozen after being dug they spoil quickly. If desired they may be dug and stored in pits like turnips, but with a somewhat lighter covering of straw and earth. The usual yield is from 200 to 500 bushels to the acre but 1,000 bushels are sometimes obtained. When land becomes infested, as it sometimes does, with the plant, pigs, for which the tubers make valuable food, may be turned loose upon the field. The tubers resemble potatoes in composition and like them are used largely in Europe for the manufacture of alcohol. The young plants are sometimes used as cattle food and the dry stalks for fuel. Consult ‘Bur or Globe Artichoke’ in United States Department of Agriculture Year Book, 1899; Circular 31 (1899); Bailey, ‘Cyclopædia of American Horticulture’ (1900–02); Vilmorin, ‘The Vegetable Garden,’ translation by Robinson (1885).

Ar'ticle, in grammar, a part of speech used before nouns to limit or define their application. In the English language *a* or *an* is the indefinite article (the latter form being used before a vowel sound) and *the* the definite article. The English indefinite article is really a modified form of the numeral adjective *one;* so the German *ein* and the French *un* stand for the numeral and the article. There are traces in various languages showing that the definite article was originally a pronoun; thus the English *the* is closely akin to both *this* and *that.* The Latin language has neither the definite nor the indefinite article; the Greek has the definite; the

Hebrew and Arabic definite article was prefixed to its noun, while, on the other hand, in the Syriac and Chaldaic it was affixed to the noun, as it is in the Icelandic. In the Scandinavian language the definite article is appended to the end of the word as *hus-et,* the house.

Ar'ticles, divisions of a printed or written document or agreement. A specification of distinct matters agreed upon or established by authority or requiring judicial action. In chancery practice articles are a formal written statement of objections to the credibility of witnesses in a cause in chancery, filed by a party to the proceedings, after the depositions have been taken and published. The object of articles is to enable the party filing them to introduce evidence to discredit the witnesses to whom the objections apply, where it is too late to do so in any other manner (2 Daniel Chan. Pr. 1158), and to notify the party whose witnesses are objected to of the nature of the objections, that he may be prepared to meet them. Upon filing the articles a special order is obtained to take evidence. The interrogatories must be so shaped as not to call for evidence which applies directly to facts in issue in the case. 3 Johns. Ch. N. Y. 558. The objections can be taken only to the credit and not to the competency of the witnesses. 3 Johns. Ch. N. Y. 558; 3 Atk. Ch. 643, and the court are to hear all the evidence read and judge of its value. 2 Ves. Ch. 219.

Articles of Agreement.— A written memorandum of the terms of an agreement. They may relate either to real or personal estate, or both, and if in proper form will create an equitable estate or trust such that a specific performance may be had in equity. The articles of agreement should contain a clear and explicit statement of the names of the parties, with their additions for purposes of distinction, as well as a designation as parties of the first, second, etc., part; the subject-matter of the contract, including the time, place, and more important details of the manner of performance; the covenants to be performed by each party; the date, which should be truly stated. It should be signed by the parties or their agents. When signed by an agent the proper form is, A. B., by his agent(or attorney), C. D.

Articles of Confederation.— The title of the compact which was made by the 13 original States of the United States of America. It was adopted and carried into force 1 March 1781 and remained as the supreme law until the first Wednesday of March 1789.

Articles of Faith.— Summarized statements of religious views relating to the central doctrines of a theological system. Protestant divines divide these into fundamental and non-fundamental articles. Familiar examples of articles of faith are the Nicene, Apostles', and Athanaisan creeds, the Thirty-Nine Articles, the Westminster, Augsburg, and Helvetic Confessions. See CREED.

Articles of Impeachment.— A written articulate allegation of the causes for impeachment. Blackstone calls them a kind of bill of indictment, and they perform the same office which an indictment does in a common criminal case. They do not usually pursue the strict form and accuracy of an indictment, but are sometimes quite general in the form of their allegations. They should, however, contain so much certainty as to enable a party to put himself on the proper defense, and in case of an acquittal to avail himself of it as a bar to another impeachment. Additional articles may perhaps be exhibited at any stage of the proceedings. The answer to articles of impeachment is exempted from observing great strictness of form, and it may contain arguments as well as facts. A full and particular answer to each article of the accusation should be given.

Articles of Partnership.— A written agreement by which the parties enter into a partnership upon the conditions therein mentioned. The instrument should contain the names of the contracting parties severally set out; the agreement that the parties do by the instrument enter into a partnership, expressed in such terms as to distinguish from a covenant to enter into a partnership at a subsequent time; the date and necessary stipulations, some of the more common of which follow. The commencement of the partnership should be expressly provided for. The date of the articles is the time, when no other time is fixed by them. The duration of the partnership should be expressly stated. It may be for life, for a limited period of time, or for a limited number of adventures. When a term is fixed it is presumed to endure until that period has elapsed, and when no term is fixed, for the life of the parties, unless sooner dissolved by the acts of one of them, by mutual consent, or operation of law. The duration will not be presumed to be beyond the life of all the partners, but provision may be made in the articles for the succession of the executors or administrators or a child or children of a deceased partner to his place and rights. Where provision is made for a succession by appointment and the partner dies without appointing, his executor or administrators may continue the partnership or not at their option. A continuance of the partnership beyond the period fixed for its termination, in the absence of circumstances showing intent, will be implied to be upon the basis of the old articles (15 Ves. Ch. 218), but for an indefinite time. The nature of the business and the place of carrying it on should be carefully stated. An injunction will be granted by a court of equity when one or more of the partners endeavors, against the wishes of one or more of them, to extend such business beyond the provision contained in the articles. The name of the firm should be ascertained. The members of the partnership are required to use the name thus agreed upon, and a departure from it will make them individually liable to third persons or to their partners in individual cases. The management of the business, or of some particular branch of it, is frequently entrusted by stipulation to one partner, and such partner will be protected in his rights by equity, or it may be to a majority of the partners, and should be where they are numerous. The manner of furnishing capital and stock should be provided for. When a partner agrees to furnish his proportion of the stock at stated periods, or pay by installments, he will, where there are no stipulations to the contrary, be considered a debtor to the firm. Sometimes a provision is inserted that real estate and fixtures belonging to the firm shall be considered as between the partners, not as partnership, but as individual property. In cases of bankruptcy, this property will be treated

as the separate property of the partners. The apportionment of profits and losses should be provided for. The law distributes these equally, in the absence of controlling circumstances, without regard to the capital furnished by each. Periodical accounts of the property of the partnership may be stipulated for. These, when settled, are at least *prima facie* evidence of the facts they contain. The expulsion of a partner for gross misconduct, bankruptcy, or other specified causes may be provided for, and the provision will govern when the case occurs. A settlement of the affairs of the partnership should always be provided for. It is generally accomplished in one of the three following ways: *First*, by turning all of the assets into cash, and after paying all the liabilities of the partnership, dividing such money in proportion to the several interests of the parties; or, *second*, by providing that one or more of the partners shall be entitled to purchase the shares of the others at a valuation; or, *third*, that all the property of the partnership shall be appraised, and that after paying the partnership debts it shall be divided in the proper proportions. The first of these modes is adopted by courts of equity in the absence of express stipulations. Submission of disputes to arbitration is frequently provided for, but such a clause is nugatory, as no action will lie for a breach.

Articles of War.— A code of laws for the regulation of the military forces of a country. In the United States the articles of war form an elaborate code, thoroughly revised in 1880, but subject at all times to the legislation of Congress. Those of Great Britain and Ireland were issued prior to 1879, in pursuance of the annually renewed mutiny act. In 1879 the army discipline act consolidated the provisions of the mutiny act with the articles of war. This act was amended in 1881, and now the complete military code is contained in the army act of 1881.

Ar'ticles, The Six. In English Church history these were articles of faith imposed by the Act 31 Henry VIII. cap. xiv., passed by Parliament in 1539, and known as the Six-stringed Whip or Bloody Statute, from the merciless persecutions to which it gave rise. They are supposed to have been the composition of King Henry himself, and they had no formal authority from the Church. They enforced belief in transubstantiation; declared communion in both kinds unnecessary; the marriage of priests was unlawful; that vows of chastity or widowhood were absolutely binding; and that private masses and auricular confession were expedient and necessary. The severity of the act was soon mitigated, and it was finally repealed in the first year of Edward VI.

Ar'ticles, The Thirty-nine, of the Church of England, a term applied to a body of divinity, chiefly founded on the formulary of Forty-two Articles compiled by Archbishop Cranmer in 1551, in obedience to the command of Edward VI. and the privy council, who instructed him to "frame a book of articles of religion, for the preserving and maintaining peace and unity of doctrine in this Church, that, being finished, they might be set forth by public authority." Several of these articles (the 1st, 2d, 25th, and 31st) were drawn directly from the Augsburg Confession, and the 9th and 16th are traceable to the same source. During the reign of Mary the Articles were suppressed, but the accession of Elizabeth offered an opportunity of drawing up a fresh formulary. In 1562–3 a convocation was held, in the course of whose sitting King Edward's Articles were carefully considered and revised. As the result of this revision (mainly the work of Archbishop Parker, assisted by Bishops Grindal, Horn, and Fox), four of the original 42 articles were omitted, namely, the 10th, 16th, 19th, and 41st, and articles 5th, 12th, 29th, and 30th were newly introduced; 17 other articles were more or less modified. On a further revision articles 39th, 40th, and 42d were struck out, and some slight changes made in several others. These 39 articles were drawn up and ratified in Latin, but when printed both in Latin and English the 29th was omitted and the first clause of the 20th struck out. The 39th was, however, restored on a final revision by Parker in 1571, and then imposed on the clergy for subscription. They were ratified anew in 1604 and 1628. All candidates for ordination must subscribe these articles, but subscription is no longer necessary on matriculating or taking a degree at Oxford or Cambridge. This formulary is now accepted by the Episcopalian Churches of Scotland, Ireland, and America.

The first five articles contain a profession of faith in the Trinity, the incarnation of Jesus Christ, his descent to hell, and his resurrection, and the divinity of the Holy Ghost. The three following relate to the canon of the Scripture. The 8th article declares a belief in the Apostles', Nicene, and Athanasian creeds. The 9th and following articles contain the doctrine of original sin, of justification by faith alone, of predestination, etc. The 19th, 20th, and 21st declare the Church to be the assembly of the faithful, and that it can decide nothing except by the Scriptures. The 22d rejects the doctrine of purgatory, indulgences, the adoration of images, and the invocation of saints. The 23d decides that only those lawfully called shall preach or administer the sacraments. The 24th requires the liturgy to be in English. The 25th and 26th declare the sacraments effectual signs of grace (though administered by evil men), by which God excites and confirms our faith. They are two: baptism and the Lord's Supper. Baptism, according to the 27th article, is a sign of regeneration, the seal of our adoption, by which faith is confirmed and grace increased. In the Lord's Supper, according to article 28th, the bread is the communion of the body of Christ, the wine the communion of his blood, but only through faith (article 29); and the communion must be administered in both kinds (article 30). The 28th article condemns the doctrine of transubstantiation, and the elevation and adoration of the Host; the 31st rejects the sacrifice of the mass as blasphemous; the 32d permits the marriage of the clergy; the 33d maintains the efficacy of excommunication. The remaining articles relate to the supremacy of the king, the condemnation of Anabaptists, etc.

Artic'ula'ta, a name given by Cuvier to a branch of the animal kingdom embracing the worms (*Annulata*) and *Arthropoda*. The group is not now considered a natural one, and has been subdivided into several branches or phyla.

Ar'ticula'tion. See JOINT.

Artificial Camphor, a product manufactured from turpentine. The sap of the pine tree after it is distilled and purified is the turpentine of commerce. A couple of thousand pounds of this material is placed in great steam reaction tanks; these are covered with asbestos to retain the heat. A quantity of oxalic acid, which is rich in oxygen, is likewise placed in the reaction tanks, together with the turpentine, and when the chemical action resulting from the union has been completed two new chemicals are formed and are known as pinol oxalate and pinol formate, respectively. These are in liquid form and are conveyed to a set of distilling tanks by means of a force pump; in these tanks a new element is introduced in the form of an alkali, and when mixed with the liquid live steam is turned on. After distillation camphor results, together with some of the essential oils, such as oil of lemon and others, but these are dissolved in the reaction products, which also contain a kind of camphor termed borneol.

Ar'tifi'cial Flow'ers, flowers manufactured from cloth or other substances in close imitation of natural flowers, for purposes of ornament. The leaves and petals are generally made of silk or cambric punched out to proper shapes and sizes. These are tinted with a brush and color, and if necessary glazed with gum or sprinkled with fine flock to imitate the glossy or velvety surface of natural flowers. The ribs, where present, are indented with a warm iron. The stamens and pistils are formed of wire covered with silk and dipped in gum-water to form the anthers. The stalk is then made of wire, coated with green paper, and fixed to the stamens and pistil, around which are attached the petals, and lastly the calyx. Buds are made of cotton or glass balls covered with cambric of a proper color. This industry has been successfully carried on in the United States, where a large number of women are constantly employed in making artificial flowers. The coloring matter, however, used for these articles is often nothing less than the deadly poison arsenic. Hoffman and other chemists have shown that the most terrible effects may spring from the use of these arsenical compounds.

Ar'tifi'cial Limbs, substitutes for human arms and legs and parts thereof, the manufacture of which has received the attention of surgeons and mechanics from a very early date. In the great work on surgery by Ambrose Paré, in 1579, he refers to and gives detailed illustrations of an artificial arm and leg, and although the construction was of a rude character they showed a very good attempt to conceal the mutilation. In 1696 an artificial leg was invented by Verduin, a Dutch surgeon. It was composed of a wooden foot, to which was fastened two strips of steel extending up to the knee. To these strips was riveted a copper socket to receive the stump; a leather for lacing around the thigh was connected to the socket by two steel side-joints, thus dividing the points of support between the thigh and stump. The construction of this leg was improved later by Prof. Serre of Montpelier. Improvements and new limbs were more recently introduced into England and France by Fred. Martin, M. Charrière, MM. Mathieu and Bechard, but these were mostly unprotected by patents. Thomas Mann secured patents for artificial limbs 20 Jan. 1790, and 1810. James Potts of England patented a new leg 15 Nov. 1800. This soon became celebrated as the «Anglesea leg,» because it was so long worn by the Marquis of Anglesea. An improvement on this leg was patented by William Selpho, who was the first manufacturer of note in New York, where he established himself in 1839. Other inventors and manufacturers soon took a great interest in the business — so many, in fact, that the American patent office shows a record of about 150 patents on artificial legs, or more than double that of all European patents on limbs. The Civil War, which caused the mutilation of so many soldiers and sailors, and the liberality of the government in supplying their losses with artificial limbs, naturally stimulated the efforts of inventors in producing such substitutes as would be accepted. These soldiers and sailors are supplied once in every five years, and to this demand is added that of those who have lost limbs from disease or accident, making in all about 100,000 in the United States who have to be supplied with new limbs on an average of about once in every five to eight years. The perfection to which limbs have been brought is wonderful and very interesting. A person with two artificial legs can walk so perfectly as to avoid detection, and a person with a single amputation can almost defy detection. Notable improvements in artificial limbs, and more particularly in legs, were made by C. A. Frees of New York. One of these improvements, and one of the most important, consists in the movements of the knee and ankle joints, by which the whole limb is strengthened and made more durable. An important feature of this piece of mechanism consists in the introduction of a universal motion at the ankle-joint, imitating the astragalus movement with an additional joint, and thus producing a most perfect artificial substitute. Another of his improvements of equal importance, is in the knee-joint of the leg for thigh amputation, which is so arranged that when in a sitting position the cord and spring are entirely relaxed, relieving all strain and pressure; and when rising to an upright position the cord and spring are again brought into proper position without strain or unnatural movement, no extra attachments being required. Artificial arms and extension apparatus for short legs are also wonderful examples of American ingenuity.

Ar'tifi'cial Respira'tion. See ASPHYXIA; DROWNING (*Treatment*); RESPIRATION.

Artificial Stone, a combination of hydraulic cement, broken stone, sand, etc., cemented together. There are many varieties, some of which are exceedingly valuable for building purposes, especially in localities where building-stone is not readily obtained. Cements thus made increase in strength and solidity for an indefinite period. This stone is in constantly increasing demand. For the various kinds and uses see CEMENT.

Artigas, är-tē'gas, **Fernando José,** a South American soldier, dictator of Uruguay: b. Montevideo, 1755; d. in 1851. In 1811 he joined the revolt of Buenos Ayres against Spain, whose troops he repeatedly defeated; but acting for himself was outlawed by the insurrectionary junta, whose troops in turn he routed and compelled it to cede Uruguay to him in 1814. He then assumed the dictatorship, but in 1820 was

defeated and fled to Paraguay, where the dictator Francia banished him to Candelaria. Thereafter he devoted himself to agriculture and philanthropy.

Artil'lery (a restricted use of a word properly meaning simply "works of skill," "clever inventions"): (1) All firearms too heavy to be carried in the hand and therefore rested on carriages or masonry foundations; (2) the division of army or navy which uses such arms; (3) the science treating of their theory and practice. The first is divided into *horse* artillery,— light guns mainly for cavalry use, with mounted gunners, and much the same as *flying* artillery, for rapid evolutions in the field, whose gunners are either mounted or ride on the gun-carriages of ammunition wagons when moving; *field* artillery, for general infantry service,— sometimes used to include the foregoing, but commonly specialized to mean the same as *foot* artillery, with unmounted gunners; (*light* artillery includes both these classes, as distinguished from the following); and *heavy* artillery,— all that is not mobile enough for field evolutions,— divided into *siege* or *garrison* artillery, for breaching the walls of fortresses or defending field works, and *coast* artillery, for permanent works, with carriages too heavy for transport, classed as siege, casemate, barbette, and mortar carriages.

A *park* of artillery is a complete set of artillery equipment,— including the guns, carriages, caissons (see AMMUNITION, under "ammunition wagons"), repair outfit, harness, field forges, etc., — gathered in one spot, in barracks or in action; in the latter case the reserve equipment is "parked" out of range of the enemy's fire. A *train* of artillery is a certain number of pieces mounted on carriages and with all their furniture, ready for marching. "Artillery carriages" means either wagons for carrying ammunition or supplies, as above; or gun-carriages, to draw the guns with or fire them from, which may be either stationary as for coast service and permanent works, or movable as in field service. The part which rests on the ground in firing is called the *trail;* the detachable pair of wheels by which it is drawn about, in addition to the fixed pair, is called the *limber*, and the gun is said to be "unlimbered" when they are taken away to let the gun be served, and "limbered up" when they are attached.

The old word "cannon" is not now used by professionals, but "gun" instead. The volume of a gun's service is defined either by the diameter of its bore, as 6-inch, 12-inch, etc.; or by the weight of the spherical iron solid shot it holds, as 12-pounder, 18-pounder, etc. (often abbreviated to 12's, 18's, etc.). The latter characterization has long been used to denote calibre only, without reference to the actual weight of the projectile it fires: thus, a 12-pounder may fire a 30-pound conical shell. This is necessarily so since the entire disuse of spherical shot (see AMMUNITION).

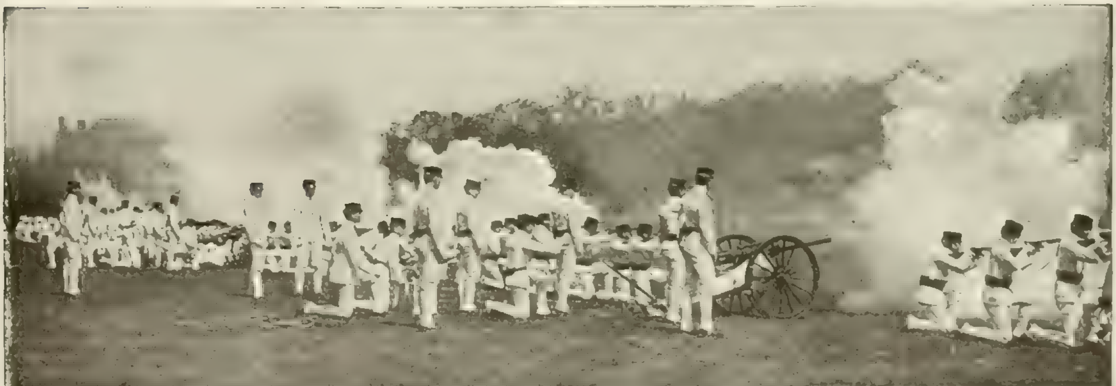
The relation of artillery to small-arms was essentially the same before the invention of gunpowder as afterward: hand-arms, as arrows, darts, slings, swords, etc., corresponded to small-arms and the bayonet; while the artillery consisted of machinery too heavy to be held up, for throwing large projectiles, the power being springs, levers, or weights. Midway between them, however,— as the matchlock arquebuse, rested on the ground to fire, was between small-arms and artillery, but a far more efficient weapon,— was the crossbow or arbalist: a heavy bow with steel or horn frame, stretched by a winch or in its larger sizes by a windlass, and shooting a notched quarrel (that is, a quadrate or square-headed bolt), or sometimes stones or balls of lead. It could be carried by a hunter, or fixed on field or deck; could penetrate armor, and was so destructive as to be prohibited by the Church except in war against the Infidel; and in the early Middle Ages was as decisive in naval or siege warfare, when well handled, as modern artillery, winning many important sea fights and others; but in the field it was too slow for the highest efficiency, as it could be fired only twice a minute. Its larger sizes were true artillery in the modern sense; and like it, but heavier, were the ballista, springal, and onager, which threw stones from a bucket or bag, also beams and masses of inflammable material, at or over walls of besieged places. The catapult, mangonel, and trébuchet (the latter a machine of surprising accuracy and power, as proved by an experimental model made by Prince Louis Napoleon in 1850, and used to breach walls) threw the same missiles by means of a spring lever balanced by a heavy weight, and held down by a windlass.

The introduction of modern gunpowder artillery is clouded by unverifiable legends and confused with the use of explosive mixtures to make a terrifying noise, and with the throwing of inflammable materials by the machines above mentioned. If the Chinese invented it, as alleged, they did it so ineffectively that the great progressive military genius Timur (1333-1405) did not think it worth using; and if the Spanish Saracens used it in Spanish sieges in the 12th century, they did not employ it against Northern foes, nor did the latter borrow it; whereas within a few years of the first verifiable European notice we have it,— a Florentine order of 1326 relating to the manufacture of cannon and iron balls, — it had gone over Europe like wild-fire. The Germans used it at Cividale, Italy, in 1331; Edward III. by at least 1338; the latter formed a regular artillery train of iron and brass cannon in 1344 (in which year also Petrarch speaks of it as familiar and common), and employed it at Crécy in 1346, though ineffectively. Naturally cannon came before small-arms: even so, the first were excessively clumsy in size and construction, —bell-shaped tubes with a touchhole for a train of priming powder set off by a fuse or red-hot iron above; made of iron bars hooped together, or of hand-hammered and bored iron, copper, or brass cylinders; and supported on immense platforms drawn by scores or even hundreds (as with Mohammed II.'s cannon at the siege of Constantinople in 1453) of draft animals, or of men. Sometimes they were not even closed tubes, but open at breech as well as muzzle, the shot being wedged in; sometimes they had no carriages, but were rolled into position and wedged or blocked there. They were mortars rather than cannon in the modern sense, being short and wide-mouthed, and sending off their balls or stones at a great elevation, and were known as bombards or vases. They were of use mainly in siege work; and it was not till toward 1500 that field artillery in its modern sense came into much use, Charles VIII.

ARTILLERY DRILL—THE FORMATION OF THE HOLLOW SQUARE.

ARTILLERY DRILL.

ARTILLERY DRILL—PREPARING TO MOVE GUNS.



ARTILLERY DRILL.

of France utilizing it in his Italian campaigns from 1488 onward.

There was no permanent artillery organization: the gunners were detailed from garrisons, and disbanded and sent back there as soon as the campaign was over; and in England the command in the field was by the Master of the Ordnance, an artillery commissary-general in effect. The transport cattle were hired or impressed, and the drivers of gun-carriages were ordinary teamsters hired by contract or secured for the occasion. Curiously, these last did not form a part of the military body till Napoleon's time.

The 16th century developed this arm greatly in volume, but not so much in science: projectile mathematics were rudimentary, and the imperfect mobility of the guns crippled their usefulness in battle — once they had fired a few rounds in advance of the troops to clear a path and cow the enemy, their service was nearly at an end, as they could not fire when their own troops were in front of them nor move in front or flank to avoid them (the battle of Pavia was lost by this); and were regularly captured and retaken as either side gained ground. Francis I., however (1515–47), lightened their make and took care to secure the best draft horses, and won Marignano (1515) with them; Louis XII. (1498–1515) owed much of his success in the Italian wars to this arm: and Charles V. (1519–55) shared in its development, his Netherland subjects being so forward in it that Henry VIII. employed Dutch gunners to instruct his men. The use of cast bronze, giving surer bore and calculability, as well as lightness for a given power, became common; the bell-shaped mortars gave place to 18-pound culverins for siege work, and to 2's, 4's, 6½'s, and 8's (called falcons, falconets, and sakers) in the field. The great difficulty of carriages also,— to find one easily drawn yet stable enough to fire from,— was partially surmounted; and in Holland the miscellaneous calibres and classes of cannon were reduced to four — 6's, 12's, 24's, and 48's. The Dutch and Huguenot religious wars in the latter part of the century developed the rudiments of a genuine system of artillery tactics, the use of the arm in connection with other arms as part of a tactical whole.

The first half of the 17th century is the first great landmark in the history of artillery. Henry IV. of France in his later years (d. 1610) occupied himself greatly with it; his minister Sully was master-general of artillery, and turned out over 400 pieces; and Maurice of Nassau (1584–1625), son of William the Silent, was much concerned with it. But its re-creator was Gustavus Adolphus (1611–32), who made it almost the centre of his system of warfare. Seeing that weight of ball was of minor consequence with the human body as a target, or length of range at close quarters, he devoted his whole attention to securing mobility and rapidity of fire. The former he obtained by putting nothing above a 12-pounder into the field, and by having a very light gun constructed, the fact that it would bear but a small charge being immaterial: it was made of a "thin cylinder of beaten copper, screwed into a brass breech, strengthened with four iron bands," the whole covered with mastic, cords, plaster, and finally boiled and varnished leather. It was called the *kalter* or the "leather gun," and could be drawn about by the two gunners who served it. But the light charge it could bear made its range too short for the best results, and later it was replaced by a four-pound iron cannon, drawn by two horses. He had also heavier guns to beat down defenses, which in retreat he protected by the lighter ones. Rapid fire he secured by inventing the cartridge instead of pouring in powder, and his cannon could be fired faster than the ordinary musket. The kalter guns were first introduced during his Polish wars; in the Thirty Years' war his success was greatly helped by his improved artillery against the Imperialists' clumsy weapons and methods. At Breitenfeld (1631), Tilly's guns were mainly 24-pounders requiring 20 horses each and 12 for the wagons, could hardly be moved in action, and were almost at once silenced by the advance of their own troops; at the Lech (1632) Gustavus converged 72 pieces on the enemy at the river bend and make a crossing practicable; at Lützen (1632), Wallenstein's batteries were practically stationary, Gustavus had heavy ones on his wings and centre and moving with them. He attached two guns to each regiment, under the colonel's orders — the "battalion system," but whose defect of dispersion of guns he corrected by also massing strong batteries to concentrate a crushing fire where needed; and he raised the total proportion of guns to 6 per 1,000 men, fully double that of any other nation. He also first saw that field and garrison service were essentially distinct, and separated the two branches of artillery not only in material but men. In England during this century, though the leather guns were used by the Scotch in 1640 on the invasion of England, and the Parliamentary army was crushed at Roundway Down (1643) by artillery, it remained in a comparatively undeveloped state, owing to the lack of the constant wars of the Continent; the complaint was made that there were no expert gunners in England.

In the latter part of the century, the perpetual wars of Louis XIV. led to a still further development of this arm. Even in the first part of his reign it was in a very primitive condition. The artillery officers had no functions whatever in time of peace, their nominal offices being purely titular; Vauban protested against this, but it was not remedied till Vallière's reforms of 1732. In 1671, however, Louvois first established a permanent organization for it, creating a regiment of artillerymen consisting of gunners and workmen, and establishing schools of instruction. The calibres were reduced in number and made uniform — those left (4's, 6's, 8's, 12's, 18's, 24's, and 32's) remain in use still, some of them rifled; bronze and iron were both used; carriages were much improved, made of wrought iron and provided with limbers, a special one invented for coast artillery, and platform wagons introduced. The development under him, however, was more in siege than field artillery. The Dutch and English introduced howitzers (a gun with a powder chamber smaller than the bore, for horizontal shell-firing, combining something of cannon accuracy with mortar calibre), mortars, and explosive shells, both hand and gun; and used canvas cartridges and grape-shot (several iron balls in a canvas case). The Woolwich arsenal was established in 1672. In 1682 the gunners were for the first time put un-

der military discipline, their function being previously considered that of civil artisans, and indeed the master gunners were carried on the civil establishment till 1783; in 1794 it was still thought needful to give the ordnance officers express authority over the gunners, by commission. William III. (1689–1702) formed the first English regimental artillery establishment, in place of detailing men from other arms as needed. England, however, was relatively backward.

The first half of the 18th century saw great extension of the specializing in this arm, and the quality of its items; but not very much invention. In France, Vallière the elder, a practical artillery general of immense ability, made great improvements; he reduced the calibres to five; lengthened the pieces, on the ground that short ones had less range and less accuracy, less ricochet and greater recoil, took more munitions and transport for equal service, and could not be used in sieges; he also greatly extended the training schools, and the continued practice of the arm in time of peace. Less usefully, he fought with success against separating the field artillery from the engineers, as involving two artillery trains instead of one. In England, Marlborough used it with effect as it was; the "Royal Regiment of Artillery" was formed in 1716 (the present body in 1722), and in 1741 the Royal Military Academy was instituted at Woolwich. The manufacture and service were both greatly improved; the English artillery was noted "for its lightness, elegance, and the good quality of its materials." The guns in use at the middle of the century were 24's, 12's, 6's, and 3's, in "brigades" (batteries) of four, five, and six guns, divided into light and heavy brigades; each field gun drawn by four horses, the two leaders driven by artillerymen. In Frederick's wars, the English artillery won great distinction. Frederick himself hardly valued this arm at its full value till the melting away of his trained soldiers compelled him to rely upon it more and more. This was perhaps rather from the extremely poor state in which his father left it, than from lack of understanding; that he realized at least a part of its defects and its importance is shown by the fact that finding the gunners and engineers mostly mechanics of inferior grade, he at once drafted the worst of them into garrisons, replacing them with men of competence and position; and as they had no commissions, and were consequently scorned by the other arms of the service, he gave the officers commissions and extra pay, and ranked them with officers of the guards. But his father had given all his attention to the drill and discipline and physical magnitude of his soldiers, to the neglect of the artillery, which at his death consisted of only one battalion of field and one of garrison, of six and four companies respectively; and Frederick inherited his general policy, though with a larger mind. His artillery was vastly nferior to the Austrian, raised to a preeminent position by Prince Lichtenstein. There were two pieces to a battalion, directed by a corporal without independent authority, and the battalion commander had enough on his mind without attending to artillery, which were expected always to keep a certain distance in advance of the troops, thus scanting their time to fire during an advance, and were usually captured in a sudden retreat from lack of time to limber up. Still they did good service at Rossbach, Hochkirchen, and Leuthen; and Frederick raised the proportion of guns to men, and in 1759 formed the first battery of horse artillery, of 6-pounders and 7-pound howitzers — placing great reliance on howitzers, making much use of them against intrenchments, and after the war attaching 40 heavy pieces to each corps. With only 2½ or 3 guns per 1,000 at the outset, he ended with 5 or 6; he created a horse artillery almost as rapid as cavalry; and although at the beginning of the Seven Years' war he had made the error Gustavus avoided, of using too heavy pieces in the field, he grew to appreciate mobility better, and gradually replaced them by lighter ones, saving the others for siege and garrison guns. His wars made three important changes in artillery tactics: the distribution of small batteries at important points in place of concentrating large ones on centre and flank; the preparation for an advance and the protection of deploying columns by light guns; and the rapid change in position of batteries, made possible by the horse artillery. The latter was employed by the Russians also, each regiment having three howitzers with mounted gunners.

The greatest artillery result of Frederick's wars, however, was in France. This country had been very backward in that arm since Louis XIV.'s time, ammunition and transport being especially crude. In 1765 Gen. Gribeauval, termed the "father of the modern artillery system," — who had held an artillery command under Lichtenstein in the Seven Years' war, and admired the efficiency of the Austrian system,— undertook to reconstruct the French one from the bottom; for many years the fierce resistance he encountered made it impossible, though he succeeded in reorganizing the personnel; but in 1776 he became inspector-general of artillery, and carried through the rest of the most far-reaching reform ever effected in this arm, much of it permanent to this day. He divided it into field, siege, garrison, and coast artillery, with a separate class of material and separate personnel for each. For all material a uniform construction was adopted, tables of construction drawn up, and all possible parts made interchangeable. For lightness and consequent mobility, he made the pieces perfectly plain, reduced the length and weight of field pieces, which he restricted to 12's and under (guns in embrasures or behind parapets, of course, could not be shortened), reduced the charge, and therefore the necessary windage (the difference between the diameter of the projectile and that of the gun-bore). Field guns were limited to 4's, 8's, and 12's, and 6-inch howitzers. In ammunition the old grape and case shot were replaced by sheet-iron canisters holding cast-iron balls. Accuracy of fire was vastly improved by elevating screws and tangent scales, the latter based on the mathematical discovery that the path of a projectile is not flat. For siege and garrison guns he adopted at first the 12's and 16's, 8-inch howitzer, and 10-inch mortar; in 1785 the 8-, 10-, and 12-inch "gomer" mortar (with conical bore). The carriages were strengthened, lightened in draft, and improved in mechanism, and ammunition chests affixed; trunnion poles and the *prolonge* rope (to unite limber with trail, for firing in slow retreat) introduced, and the horses harnessed in pairs instead of tan-

dem; and the *bricole* devised — a collar with rope and hook to which the gunners and foot-soldiers harnessed themselves. A new ammunition wagon carrying fixed ammunition was built. Siege carriages had shafts in place of the field carriages' poles; garrison carriages, wheels in front and a truck in the rear; for coast service there were traversing platforms, with bolt in front and truck in rear on a circular racer. The field artillery was divided into regimental guns and corps or reserve artillery; the latter was subdivided into divisions of eight guns of the same calibre, and a company of artillery assigned to each brigade of four battalions. Eight pieces were also attached to the centre and to each wing. Horse artillery was not introduced till 1791, and horsemen and gunners were combined, each learning the other's work.

In the wars of the French Republic, in 1793, when the divisional organization was adopted, guns were attached to the divisions as well as to battalions; in 1796 Napoleon withdrew them from the latter and abolished the old "battalion system," to the great advantage of both arms, the infantry regiments being impeded by the guns and the guns ill served by the divided command. In 1800 he took the last step in professionalizing the arm, by establishing a driver corps of soldiers in place of outside teamsters. His only change in guns was substituting the 6-pounder of the 8's and 4's, and the use of a 24-pound howitzer, but his tactical improvements were great. He employed with enormous effect the modern system of massing gunfire on selected spots, and could not have won his prodigious victories without it, and like Frederick, as his soldiers were swept away he increased his artillery force, rising from 2½ to about 4 per 1,000. His tactics are still part of the instruction of all soldiers.

The British began their long struggle against France very ill-equipped in all military points, and in none more so than artillery; guns, ammunition, transport, were alike crude and ill arranged, the whole equipment hardly able to move faster than foot pace. The field artillery was simply garrison artillery drafted into the field. Field and siege guns were intermingled, in batteries of 12, each battalion having two; the horses were in tandem of three, the drivers carters on foot. In the years before the Peninsular war (1808–14), however, Major Spearman had transformed it. Horse artillery was introduced in 1793; a battery consisting of two 9's and three 6's (later of 9's wholly), and a 5½-inch howitzer. A driver corps was formed in 1794, consisting of a few subalterns, non-commissioned officers, artificers, civilian drivers and horses — divided into "troops," one added to each company of foot artillery. Battalion guns were abolished in 1802, and six-gun field batteries organized, each of five 6 to 12-pounders and a 5½-inch howitzer; the drivers were to be soldiers; the horses were teamed in pairs, drivers on the off ones, and eight gunners carried on the limbers and wagons. The equipment was lightened and simplified, and ammunition well packed instead of flung into rough boxes. Excellent additions were made to material by the invention of shrapnel shell by Major Shrapnel in 1803, and by the development of the antique rocket from a mere fire-signal to a powerful engine of destruction, by Sir William Congreve in 1806 — the latter first used at Copenhagen in 1807, employed with great efficiency at Leipsic in 1813, in the Peninsular war at the Adour, and in the War of 1812 at Bladensburg.

Between 1815 and the Crimean war, the most considerable changes in material were the invention of a powerful 12-pounder howitzer weighing only 220 pounds, for mountain service, used with great effectiveness in the French campaigns in Algeria, the gun-carriage and ammunition going on muleback; the introduction in 1852 by Louis Napoleon — a hereditary artillery student, and the great work on artillery under his auspices is still a standard — of a 12-pounder to fire either solid shot or shrapnel, known as the "12-pounder Napoleon," and made the sole equipment of a set of field batteries, which did great service in his war of 1859 with Austria; and the application of rifling, though not efficiently developed till later, its use at Sebastopol being a failure. Carriages and ammunition wagons were also improved so that the gunners could ride on them, much increasing mobility; the trail was strengthened; and ammunition was carried in boxes on the limber. French field batteries, from 1827, consisted of four 12's and two 6-inch howitzers, or four 8's and two 24-pound howitzers. In England in 1820 the horses for guns and wagons were increased from six and four to eight and six respectively. In 1822, and in 1829 in France the driver corps was abolished, men being enlisted as «gunners and drivers,» and distributed among the battalions; naturally it worked ill, few men being adepts in gunnery and horse management at once. In 1848 in England, the horse artillery was raised from the two guns, to which it had been skeletonized after 1815, to four, and in 1852 to six, as was the foot artillery; and 20 batteries were formed, several more being added in 1855. Even so, this arm was badly undermanned, and deficient in both number and weight of guns, in the Crimean war, where it was organized in position batteries, with 18's and 8-inch howitzers; heavy field, with 12's and 32-pounder howitzers; field, with 9's and 24-pounder howitzers; horse, with 6's and 12-pounder howitzers; and mountain, with 3's and 4-inch howitzers — each field and horse battery having a rocket section. The French organization was horse artillery, with mounted gunners; line or field, with gunners riding on the ammunition chests; and siege or reserve, with gunners on foot. As the war consisted mainly of the siege of Sebastopol, the field artillery had little scope, though used with notable effect at the Alma and Inkerman, and mortar fire causing a frightful destruction in the Redan at the end; and the relatively great increase of range and accuracy in small arms over that of artillery (not then effective at more than a mile) was making the heavier arm subordinate. Later inventions have restored the balance.

Breech-loading and rifling now come into prominence. The earliest cannon were breech-loaders, a system quicker to charge, easier to clean, and more accurate in adjustment of missile to bore, and thus needing less windage than muzzle-loading. But till lately, mechanical science was not equal to its requirements of nice adjustment, and muzzle-loading superseded it. The defect of smooth-bores, with their straight projectile motion, is inaccuracy at long ranges:

since, as a projectile's centre of gravity rarely coincides with its longitudinal axis, the farther it goes the more its unevenness of mass carries it out of the initial path. A whirling motion corrects this by constantly restoring the balance and carrying it the other way; and this is provided by spiral grooving of the gun channel, which was invented by a German early in the 16th century, but like the other system, was in advance of mechanical development. In 1846 it was for the first time practically applied to ordnance, and rifled siege guns were used against Sebastopol, but they were still too imperfect for efficiency. In 1858 rifled 12's and 4's were adopted by France, and in the Franco-Austrian war of 1859 were used with great effect, increasing the accurate range from 1,450 to 2,500 yards, or nearly double; while the Austrians, for generations pre-eminent not only for handling but material, had only smooth-bore 6's and 12's, and 32-pounder howitzers, with the lesser range. The nature of the country stinted the service of artillery, but it was well developed at Solferino and brilliantly handled by the French at Medole. In 1860 the introduction of the Armstrong rifled breech-loader, first used in the Anglo-Chinese campaign of that year, led to a transformation of English artillery equipment: 7-inch guns, 82 hundredweight, for siege and garrison service, 40's for position batteries, 20's for same or heavy field, 12's of 8 hundredweight for light field, 9's of 6 hundredweight for horse. Field carriages were provided with a gun-metal «saddle» worked by lever and hand wheel, with elevating screw. Ammunition wagons were replaced by separate ammunition columns.

At the outbreak of the American Civil War, the United States, largely owing to Lieut. Rodman of the Ordnance Department,— inventor of the Rodman gun, whose casting by interior cooling and consequent density of channel metal, and its thickness at the seat of charge, enable it to bear a heavier charge without bursting than any other,— headed the world in artillery material: both quality and manufacture were unsurpassed. In 1861 it cast a 15-inch Rodman, the most powerful weapon known; and a 20-inch smooth-bore firing a 1,080-pound shot. Otherwise its equipment was:— Field: wrought-iron rifled 3-inch, range 2,800 yards; bronze 6's and 12's; «Napoleon» 12's, range 1,500 yards, used very effectively within it all through the war; howitzers — 12's, 24's, and 32's, and mountain 12's. Siege and garrison: Cast-iron rifled, 4½-inch; 12's, 18's, and 24's; howitzers, 24's and 8-inch; mortars, 8-inch, 10-inch, and bronze Coehorn (a small light mortar for throwing grenades). Coast (most of it at once turned into field batteries): 32's; 8-, 10-, and 15-inch Columbiads (for both shot and shell, like the Napoleons); 10-inch and 13-inch mortars. There were 18 calibres altogether — 7 of «guns,» 3 of Columbiads, 4 of howitzers, 4 of mortars. Eastern armies began with four 6-gun batteries to each division, about half of them being used as a corps reserve when corps were formed; later the batteries were reduced to four, and in 1863 taken from the divisions as formerly from the battalions, being formed into artillery brigades of 4 to 12 batteries. In the Western armies each infantry brigade had a battery of artillery till 1863, when as in the East a massing system was begun. In the Confederate armies each division had an artillery battalion of four batteries, and each corps two battalions as a reserve. This combined system has been substantially adopted by other powers. The Civil War greatly advanced the importance of artillery, and developed the Napoleonic massing system.

The short Austro-Prussian war of 1866 gave no time for new developments in military science, and in artillery service the victorious Prussians were as usual far behind the Austrians, though their material was better. They used for the first time steel breech-loading rifled guns, nominally 6's and 4's, but using 15-pound and 9-pound oblong shells with percussion fuse; the Austrians had muzzle-loading rifled 8's and 4's, in batteries of eight, employing the brigade system and rocket batteries for the last time. After this war they adopted breech-loading guns, and armed themselves from Krupp's factories.

By the time of the Franco-Prussian war in 1870 the Prussians had made great advances in artillery, and owed a part of their success to their superiority to the French, both in numbers, power, and tactics of this arm. They disused reserve artillery, attaching the batteries to divisions and corps entirely; each cavalry division had two batteries of horse artillery; they pushed their guns well in advance, preparing the way for infantry movements by concentrated fire on an objective point, and firing with deliberation at ranges from 650 to 3,300 yards; while the French wasted their fire at too long ranges, held it too long in reserve, and used it in small batteries instead of masses. Their mitrailleuses, first employed in this war, were a disappointment, though they inflicted great losses on the Prussians in carrying positions, especially when successfully masked, and clearly marked out the great future of machine guns; but for offensive work against field artillery they were not fitted. The Prussians used steel breech-loading 9's and 4's, 3.7 guns per 1,000; the French, muzzle-loading 8's and 4's, with some «Napoleon» 12's, 3 to 1,000.

In the Russo-Turkish war of 1878 nothing new of any sort was brought forward. The Turks had the better guns, the Russians much the greater number; the former used Krupp's steel breech-loaders of 3.2 and 3.5 inches, 2.2 per 1,000 men, the latter bronze breech-loading 9's and 6's, 3.9 per 1,000. In the Spanish-American war of 1898 there was little use for artillery; and the only novelty was the furnishing of smokeless powder after Santiago, when it was no longer needed. A 3.2-inch steel breech-loader and a 3.6-inch field mortar were used. As the siege train was not used, its composition is immaterial. In the Philippines and China 3.2-inch field and mountain guns were used. In the Boer war, owing to the nature of the country and the operations, artillery played but a small part, and developed no new weapons; the Boers, however, had for years laid in a stock of much more improved material than the English.

See Armament of the World; Army; Army of the United States; Ordnance; Projectiles. For ammunition see Ammunition; Explosives; Gunpowder. For the relations of the artillery arm to other services see Coast Defense; Fortification; Siege Works; Tactics.

Artil'lery Company, The Ancient and Honorable, a military organization of Boston, Mass. It was copied from that of London, was formed in 1637, and was the first regularly organized military company in America.

Artil'lery Company, The Honorable, the oldest existing body of volunteers in Great Britain. It was instituted in 1585, and comprises six companies of infantry, besides artillery, grenadiers, light infantry, and yagers. It furnishes a guard of honor to the sovereign when visiting London.

Artil'lery Corps, the official name of the entire artillery service of the United States army.

Artil'lery Schools are institutions established for the purpose of giving a special training to the officers, and in some cases the men belonging to the artillery service. An artillery school at Fort Monroe, Va., first established in 1823, discontinued, and re-established in 1867, gives instruction, both theoretical and practical. The artillery regiments of the regular army have each one foot-battery at the school. The course of instruction is one year, beginning 1 September, and it includes such subjects as ballistics, sea-coast engineering, electricity, mines and mechanisms, artillery, coast-defense, chemistry, explosives, etc. In Great Britain the artillery schools are at Woolwich and Shoeburyness. The Department of Artillery endeavors at Woolwich to give artillery officers the means of continuing their studies after completing the usual course at the Royal Military College, and of qualifying for appointments requiring exceptional scientific attainments. The school of gunnery at Shoeburyness gives instruction in gunnery to officers and men and conducts all experiments connected with artillery and stores. See MILITARY SCHOOLS.

Ar'tist's Letters from Japan, An, a work by the noted American artist, John La Farge. The drift of the book is toward a purer art; but it contains much lively matter — accounts of the butterfly dance in the temple of the Green Lotus, and of fishing with trained cormorants. A thread runs through the letters, tracing the character and progress of the usurping Tokugawa family, from the cradle of their fisherman ancestors to the graves of the great shogun and his grandson in the Holy Mountain of Nikko.

Ar'tocar'pus, the generic name of the bread-fruit tree (q.v.).

Artois, är'twä', the name of a former province of France anciently one of the 17 provinces of the Netherlands. It was bounded on the south and west by Picardy, on the east by Hainault, and on the north by Flanders. It is now almost completely included in the department of Pas de Calais. Artois is a fertile region, producing grain and hops. Its capital was Arras.

Ar'totype. See PHOTOGRAPHY.

Arts, the designation of branches of study in the Middle Ages, originally called the liberal arts to distinguish them from the servile arts or mechanical occupations. These arts were usually classed as grammar, dialectics, rhetoric, music, arithmetic, geometry, and astronomy. Hence originated the terms "art classes," "degrees in arts," "master of arts," still in common use in universities, the faculty of arts being distinguished from those of divinity, law, medicine, or science.

Aru. See ARRU ISLANDS.

Aruba, ä-roo'ba, an island belonging to Holland, off the north coast of Venezuela. It is a dependency of Caraçao and is about 30 miles long by 7 broad. The climate is healthy. Pop. about 7,700.

A'rum, a small genus of tuberous tropical and subtropical perennial herbs (commonly called callas) of the natural order *Araceæ,* with simple leaves and diversely colored convolute spathes, for which they are cultivated either under glass or, in the case of some hardy species, in the open air, as ornamental plants. The naked topped spadices bear staminate flowers just above the pistillate ones at the bases. The tender species are managed like the fancy-leaved caladium (q.v.); the hardy must be planted in rich soil in cool, moist situations and must be well mulched during the winter. *A. maculatum,* lords-and-ladies, cucoo-pint, wake-robin, from Europe, is, with its many cultivated varieties, perhaps the best known hardy species grown in America. The leaves and corms are acrid; but the latter when ripe contain starch which may be extracted and used as a food. In places where it abounds it has long been converted into a kind of arrow-root and has been proposed as a substitute for the potato, but the corms are too small for profitable culture. Some closely related native American plants of somewhat similar habit are skunk cabbage (q.v.), water calla (see CALLA), Indian turnip (see JACK-IN-THE-PULPIT). *Anthurium,* a well-known genus of greenhouse plants, is also nearly allied.

Arundel, ăr'ŭn-děl, **Thomas,** an English prelate, third son of Richard Fitz-Alan, Earl of Arundel: b. in 1352; d. Canterbury, 19 Feb. 1413. He was Chancellor of England and Archbishop of Canterbury. He concerted with Bolingbroke to deliver the nation from the oppressions of Richard II., and was a strenuous opponent of the Lollards and followers of Wyclif.

Ar'undel, Thomas Howard, Earl of. See ARUNDELIAN MARBLES.

Arundel, a small town in Sussex, England, famous as containing Arundel castle, the family seat of the dukes of Norfolk. It is on the small river Arun and has a showy Roman Catholic cathedral erected by the Duke of Norfolk. Pop. (1901) 2,738.

Ar'undel Society, a society instituted in London in 1848 for promoting the knowledge of art by the publication of facsimiles and photographs. It was named for the collector of the Arundelian Marbles.

Ar'unde'lian Marbles, a series of sculptured marbles discovered by William Petty, who explored the ruins of Greece for Thomas Howard, Earl of Arundel, in the reign of the first Stuart kings, James I. and Charles I., and devoted a large portion of his fortune to the collection of monuments illustrative of the arts, and of the history of Greece and Rome. These marbles arrived in England in the year 1627, with many statues, busts, sarcophagi, etc. John Selden published some of the inscriptions which he thought most interesting, under the title of

'Marmora Arundeliana' (1628). Henry Howard, Duke of Norfolk, grandson of the collector, presented them in 1667 to the University of Oxford, where they still remain. The whole collection of inscriptions was published by Humphrey Prideaux in 1676; by Michael Maittaire in 1732; by Chandler in 1763. These inscriptions are records of treaties, public contracts, thanks of the state to patriotic individuals, etc., and many of a private nature. The most curious and interesting is one usually known by the name of the Parian Chronicle, from having been kept in the island of Paros. It is a chronological account of the principal events in Grecian, and particularly in Athenian history, during a period of 1318 years, from the reign of Cecrops (1450 B.C.) to the archbishop of Diognetus (264 B.C.). The authenticity of this chronicle has been called in question, but has been vindicated by many of the most learned men.

Arus'pices, Roman priests and prophets, who foretold events from inspection of the entrails of sacrificed animals. They observed, too, all the circumstances which accompanied or happened during the sacrifice; for example, the flame, the mode in which the animal behaved, the smoke. The origin is to be sought for in Etruria. They were introduced into Rome by Romulus, where they flourished till the time of the emperor Constantine (337 A.D.), who prohibited all soothsaying on pain of death.

Arus'pices, On the Reply of the, an oration by Cicero. After Cicero's recall from exile different prodigies alarmed the people of Rome. The aruspices being consulted, answered that the public ceremonies had been neglected, the holy places profaned, and frightful calamities decreed in consequence. Thereupon Clodius denounced Cicero as the cause of the misfortunes that menaced the city, and on the following day the orator replied in the Senate to the attack. The speech takes rank among the greatest of Cicero's orations, though he had little time for preparation, and suffered under the disadvantage of addressing an audience at first openly unfriendly.

Aruwimi, ä'roo-wē'me, a river of equatorial Africa having its source in the hills to the west of Albert Nyanza and tributary to the Congo. Its length is a little over 800 miles and its breadth at its confluence with the Congo is about a mile. It is navigable up to Yambuya, but beyond that place there are many rapids. In its upper course it is called the Ituri. Stanley discovered its mouth in 1877 and traced a considerable part of its course in his search for Emin Pasha in 1887.

Arve, ärv, a river tributary of the Rhone, which it enters near Geneva after a course of about 50 miles. It flows through the valley of Chamouni, and many of the most famous resorts of Switzerland are found in its vicinity.

Aryabhatta, Hindu astronomer and mathematician of the 5th century: b. 476 A.D. His only known work, the 'Aryabhattiya,' is a mathematical treatise in verse; frequent reference is made to his writings by later Hindu scholars. In the solution of quadratic equations and the application of algebra to geometry and astronomy, he anticipated some of the discoveries of modern algebra. He also announced the correct theory of the diurnal rotation of the earth, and the correct explanation of solar and lunar eclipses. See ALGEBRA, HISTORY OF.

Aryan (är'yăn, or ăr'ĭ-ăn) **Languages,** an important language family frequently styled the Indo-European or Indo-Germanic family of tongues. They have reached a higher development than those of the second great family, the Semitic, and are far in advance of the next one — that comprising the Turanian tongues. Like the Syro-Arabian forms of speech they are inflectional; while those of Turanian origin are only agglutinate. Max Müller separates the Aryan family of languages primarily into a southern and a northern division. The former is subdivided into two classes: (1) The Indic; and (2) the Iranic; and the latter into six: (1) The Celtic; (2) the Italic; (3) the Illyric; (4) the Hellenic; (5) the Windic; and (6) the Teutonic. It is often said that Sanskrit, spoken by the old Brahmins, is the root of all these classes of tongues. It is more correct to consider it as the first branch and assume the existence of a root not now accessible to direct investigation. As an illustration of the affinity among the Aryan tongues the common word daughter may be instanced. It is in Swedish, *dotter;* Danish, *datter;* Dutch, *dochter;* German, *tochter;* Old Hebrew German, *tohtar;* Gothic, *dauhtar;* Lithuanian, *duktere;* Greek, *thygater;* Armenian, *dustr;* Sanskrit, *duhitri;* the last-named word signifying primarily "milkmaid," that being the function in the early Brahman or Aryan household which the daughter discharged. Not only are the roots of very many words akin throughout the several Aryan tongues, but (a more important fact) so also are the inflections. Thus the first person singular of a well-known verb is in Latin, *do;* Greek, *didomi;* Lithuanian, *dumi;* Old Slavonic, *damy;* Zend, *dadhami;* Sanskrit, *dadami;* and the third person singular, present indicative of the substantive verb is in English, *is;* Gothic, *ist;* Latin, *est;* Greek, *esti;* Sanskrit, *asti.*

Ar'yan Race, a name sometimes applied to that particular ethnological division of mankind otherwise called Indo-European or Indo-Germanic, but more properly to the Indo-Iranian group alone. The Indo-European division includes two branches, the western, which comprises the inhabitants of Europe, with the exception of the Turks, the Magyars of Hungary, the Basques of the Pyrenees, and the Finns of Lapland, and the eastern, which comprehends those of Armenia, Persia, Afghanistan, and northern Hindustan. From a multitude of details it has been established that the original mother tongue of all these peoples was the same. It is supposed that the Aryan nations were at first located somewhere in central Asia, probably east of the Caspian and north of the Hindu Kush and Paropamisan mountains. From this centre successive migrations took place toward the northwest. The first swarm formed the Celts, who at one time occupied a great part of Europe; at a considerably later epoch came the ancestors of the Italians, the Greeks, and the Teutonic people. The stream that formed the Slavonic nations is thought to have taken the route by the north of the Caspian. At a later period the remnant of the primitive stock would seem to have broken up. Part passed southward and became the dominant

race in the valley of the Ganges, while the rest settled in Persia and became the Medes and Persians of history. It is from these eastern members that the whole family takes its name. In the most ancient Sanskrit writings (the Veda) the Hindus style themselves Aryas, the word signifying "excellent," "honorable," originally "lord of the soil."

Ar'zachel, a Jewish astronomer: b. in Spain about 1050. He discovered the obliquity of the ecliptic and compiled certain astronomical tables known as the "Toledo Tables."

Arzamas, a Russian town, the capital of a district of the same name, 340 miles east of Moscow. It possesses brickyards, tanneries, and tallow factories, and in the earlier half of the 19th century was distinguished for a school of painting which furnished the greater part of Russia with ikons or sacred pictures.

As, a word which the Romans employed in three different ways: to denote (1) any unit whatever considered as divisible; (2) the unit of weight, or the pound (*libra*); (3) a coin. The *as*, whatever unit it represented, was divided into 12 parts, or ounces (*unciæ*). Scholars are not agreed on the weight of a Roman pound, but it was not far from 237.5 grains avoirdupois, or 327.1873 grammes, French measure. In the most ancient times of Rome the copper coin which was called *as* actually weighed an *as*, or a pound, but in 264 B.C. was reduced to 2 ounces, in 217 to 1 ounce, and in 191 to ½ ounce. In 269 B.C., when silver money was first struck by the Romans, the *as* was superseded as a money of account by the sestertius coined from the more precious metal.

As It Was Written, the title of a romance by Sidney Luska (Henry Harland), the scene of which is laid in modern New York. Sombre and tragic though it is, the romance shows unusual vigor of conception and execution and extraordinary intuitive knowledge of the psychology of the Jewish race.

As You Like It, the title of one of Shakespeare's comedies. Its realism lies in its gay, riant feeling, the fresh woodland sentiment, the exhilaration of spirits that attend an escape from the artificialities of society. The characters all meet in the forest of Arden, where "as you like it" is the order of the day.

A'sa, the third king of Judah. During the first 10 years of his reign his kingdom enjoyed peace and prosperity, but in the 11th year he was attacked by the Ethiopian king Zerah at the head of a vast army, which he completely routed. On his triumphant return Asa was met by the prophet Azariah, who encouraged him to persevere in the extirpation of idolatry. In the 36th year of Asa's reign Baasha, king of Israel, occupied Ramah, and proceeded to fortify it as a frontier barrier. Asa called in the aid of Benhadad, king of Syria, and recovered the city, but incurred the rebuke of the prophet Hanani for seeking help elsewhere than from the Lord. The incensed king threw the prophet into prison. He died after a prosperous reign of 41 years.

Asaba, a-sä'ba, a town in west Africa, on the Niger River, 150 miles from the coast. It is the seat of the supreme court, and contains the central prison, civil and military hospitals, and other public buildings. It is a place of large present importance, and in the evolution of new English interests in Africa may become still more conspicuous.

As'afœt'ida is a gum resin obtained from the root of *Ferula fœtida.* Although the United States pharmacopœia limits the producing plant, it is quite probable that asafœtida is obtained from two or even three or four species of *Ferula, F. narthex, F. fœtidissima, F. jaschkeanum.* The main sources, however, are *F. fœtida* and *F. narthex.* These are coarse herbs of the *Umbelliferæ* family distributed throughout the eastern Asiatic provinces from Persia, Turkestan, Afghanistan. The root is cleaned from the leaves and while growing is cut off close to the ground. This is then covered with leaves and in five or six weeks a slice is cut off, and from the cut surfaces the juice exudes. This on thickening forms the asafœtida of commerce. The chemical composition is complex. It consists of resin, gum, ethereal oil, vanillin, and ferulic acid. Asafœtida is highly prized in the East as a seasoning. In medicine it is stimulant to the sympathetic nervous system and is an excellent carminative, and stimulant of unstriped muscle fibre. It is particularly valuable in expelling flatus from the peristalsis it induces. It is also used in hysteria, but in an empirical fashion. Its further study is desirable.

Asa'ma-Yama, a-sä'ma-yä'ma, an active volcano of Japan about 50 miles northwest of Tokyo, 8,280 feet high. Its latest destructive eruption was in 1783.

A'saph, the Levite and psalmist whom David appointed as leading chorister in the temple. It is supposed that his office became hereditary in his family, or that he founded a school of poets and musicians called, after him, "the sons of Asaph."

As'arabac'ca, a European herb. See ASARUM.

As'arum, a small genus of herbs of the natural order *Aristolochiaceæ*, widely distributed in rich, shady woods throughout the northern hemisphere. They have odd chocolate or purplish, bell-shaped, three-lobed perianths containing 12 horned stamens. The flowers which are borne close to or upon the ground are hidden by the kidney-shaped or heart-shaped leaves. *A. canadense*, wild ginger, or Canada snake-root, is warmly aromatic and is sometimes used as a spice. It is common in the eastern United States and is often cultivated in wild gardens as are also the following species: *A. virginicum, A. arifolium,* both common from Virginia southward; *A. caudatum*, a Pacific coast species, *A. lemmoni* and *A. hartwegii*, both of the Sierra Nevada Mountains, the last found at altitudes of 4,000 to 7,000 feet. *A. europæum* is also cultivated. It was formerly used as an emetic, a role now played by ipecacuanha. Its leaves are still made into snuffs and are deemed efficacious as counter-irritants.

Asben, as-bĕn', a kingdom of Africa, in the Sahara, with an area of about 49,000 square miles. It consists of a succession of mountain groups and valleys and attains in its highest summits a height of over 6,000 feet. The valleys, though separated by complete deserts, are very fertile. The climate is on the whole

healthy, and not unsuitable for Europeans. The principal vegetable productions are millet, wine, dates, senna, indigo, and various kinds of vegetables.

Asbestos, one of the most remarkable substances found in nature. It is a peculiar species of the hornblende family of minerals. Its composition is chiefly silica, magnesia, alumina, and ferrous oxide, and consequently unconsumable, hence its name. The fibres formed by the chemical combination above given are perfectly smooth, and in this respect are different from all other known fibres. Paradoxically, it is the link which completes the chain between the vegetable and mineral kingdoms, and is in fact a mineralogical vegetable possessing the curious properties found in both, for it is at once fibrous and crystalline, elastic and brittle, heavy as a rock in its crude state, yet as light as thistledown when treated mechanically. Added to this, its fibres, soft, white, and delicate, have, by their inherent quality of indestructibility, withstood the action of the elements since the world began; and through all the countless ages, during which the hardest rocks surrounding it have been reduced, this mineralogical mystery has remained intact, having successfully resisted the assaults of fire, acids, and time. Asbestos is found widely distributed throughout the world, although the principal supply of crude asbestos suitable for the manufacture of fireproof cloths and curtains comes from Canada, about 75 miles from Quebec. The Italian mineral has a fine, silk-like fibre, but is lacking in the essential characteristic of strength. The product obtained from South Carolina has a soft, woody, yellowish fibre, which quickly powders under pressure. The South African asbestos, as one might naturally infer, is of a dark slate or black color, with exceptionally long, strong fibres, but owing to its stiff and horny texture, it cannot be manufactured into a fine fabric, hence the superiority of the Canadian asbestos, and its large consumption in the United States.

The mining of asbestos differs radically from the mining of other minerals, since no shafts are sunk, but excavations are made in the open, somewhat after the manner of a stone quarry. Canadian asbestos, however, is found in narrow veins or seams about an inch and a quarter in thickness, and embedded in rock which is easily severed from it. The strata of asbestos, which may be vertical or horizontal, are found in practically detached deposits, and are as elusive as those of zinc-bearing ore, and can only be determined by exploring for them. The rock to which the mineral is attached shows on fresh fracture a serpentine mineral of a green shade containing finely divided particles of chromic and magnetic iron. The asbestos on cleavage presents a brilliant, dark-green surface by reflected light, but the fibres after they are detached are perfectly white. The act of separating the mineral from its matrix of rock is termed "hand cobbing," and after this process the mineral is shipped to various factories in the United States.

The process of manufacture begins by placing the asbestos mineral in a chaser mill, a machine comprising a rotating edge-wheel revolving at the end of a radial arm in a trough, which crushes the mineral, dividing the fibres without destroying them. The result is a snowy mass of mineral wool ready for winnowing, a method of removing the minute particles of rock still clinging to the fibres very much like the winnowing of grain; this is done by means of a blast of air, which separates and blows away the foreign matter, leaving the fibres in a refined state and in proper condition for the third stage of manufacture. This is termed air fibre raising, and as the name implies, the fibres are raised by a current of air produced by a blower of large dimensions through a vertical pipe inclined at a small angle. The object of this procedure will be obvious, when it is stated that the air blown across the fibres causes those of coarser texture to be deposited in a compartment near the bottom of the pipe. The medium fibres will be projected a little higher, and these will fall into a second compartment. The finer fibres will be blown to a higher point, and there collected, while the dust will be carried to the top and deposited. The fibres are in this way sorted into different lots according to their texture, and are ready to be made into articles for which they are best adapted. The fluffy stuff now goes to the carding room, just as though it were genuine wool sheared from a sheep or pure cotton fresh from the plant on which it grows, instead of a mineral substance that in its original state was mined like a lump of anthracite coal. A carding machine, similar to that employed in preparing wool, cotton, or flax fibres before spinning, has been adopted by the manufacturers. The problem of mechanically combing these fibres was no small one, and the carding takes place in a machine having a large central rotating cylinder covered with card clothing, that is, strips of leather set with projecting wires termed teeth. Around the main cylinder there are a number of smaller cylinders, also provided with card clothing, which engages the teeth of the central cylinder rotating in the reverse direction. This machine straightens out the fibres and lays them parallel; after passing through the first breaker, they are fed into a second carding engine or breaker, which is set to a finer gauge than the preceding. A third and last carding process takes place in a machine called a finisher or condenser, when all the irregularities are eliminated, and the fibres are stripped from the final cylinder by means of a fly-comb and are converted into unspun threads, when they are delivered on a traveling apron or endless band, and are gathered into rows by reciprocating scrapers; they are then condensed, and the process is continued in the coiling cans. In spinning the yarn, the rovings are delivered to the spindles on a carriage, which then recedes, when the fibres are twisted, and returns when the spun asbestos yarn is wound on the spindles. The spinning frames do not draw the yarn, and no strain is placed on it until after it is twisted. This brings the manufacture of the fireproof material to a point where it is to be woven into cloth, packing, or other forms; for asbestos is used for divers other purposes than those appertaining to theatres.

While adulterated asbestos may be used in some of the mechanical arts, for theatrical hangings its purity should be 100 per cent; it then forms one of the safest barriers against the calamity of fire. As a matter of fact, much of that which is termed commercially pure asbestos cloth contains from 5 to 20 per cent of combustible matter, but absolutely pure Amer-

ican-made cloth may be obtained, where price is not a primary consideration. Not only is purity essential in asbestos cloth where used for protection against fire, but strength as well; and after asbestos is subjected to a high temperature, it has a tendency to powder, when, owing to its weight, it may break through, and its utility be impaired.

One of the leading manufacturers has made an improvement in weaving asbestos cloth for theatre curtains; it consists of two strands of asbestos spun around a strand of high-temperature-melting brass wire, so that the wire is completely embedded and concealed. These asbestos metallic strands form the warp, so that the threads run the long way of the cloth when finished. The weft, or filling-in cross threads, is made of plain, pure asbestos. Such a curtain will stand well under a severe high-temperature test without breaking. Not only theatre curtains, but set scenery of all kinds may be constructed of asbestos. Scenic artists find it more difficult to paint, but the finer textures may be utilized for this purpose; and although asbestos cloth does not take colors as satisfactorily as cheese cloth and burlap, yet its use should be provided for wherever audiences are to be assembled. Flooring and woodwork in general may be easily replaced by compressed asbestos fibre board, and it has been shown that the latter may be stained, polished, and finished to as high a degree as wood. All the upholstery should be of pure asbestos cloth, and carpeting is also made to take the place of the combustible vegetable and animal fibres now used so extensively. One of the peculiar properties of asbestos carpeting is that the longer it is in service, the tougher it becomes.

Asbestos is utilized in the arts in many other forms than cloth; it may be worked into a pulp, and a fireproof paper is obtained. This paper is now used on roofs, between walls, flooring, etc. Fireproof rope three eighths inch in diameter for the suspension of curtains and other uses is made, having a tensile strength of 1,650 pounds per foot. High-grade asbestos plaster is fireproof, soundproof, and hangs together with great tenacity when subjected to water. Asbestos mineral with rock as it comes from the mine costs $200 per ton, but after it is stripped the long fibres are worth $1,500 per ton. When these are made into cloth it sells for $3 per square yard; when made into curtains, the sewing is done with asbestos thread.

Asbjörnsen, as-byĕrn'sĕn, **Peter Kristen,** a Norwegian folklorist: b. in Christiania, 15 Jan. 1812; d. there, 6 Jan. 1885. While pursuing botanical and zoological studies, and subsequently during various travels at government expense, he collected folk tales and legends, aided by his friend Jörgen Moe, with whom he published 'Norwegian Folk Tales' (1842–4); and 'Norwegian Gnome Stories and Folk Legends' (1845–8; 3d ed. 1870), pronounced by Jacob Grimm the best fairy tales in existence.

Asboth, ŏsh'bōt, **Sandor (Alexander),** a Hungarian-American soldier: b. in 1811; d. in 1868. He came to America with Kossuth in 1851, and became a United States citizen, serving in the Civil War in the Federal army, attaining the rank of a brevet major-general. He was United States minister to Argentina at the time of his death.

Asbury, ăz'bĕr-ĭ, **Francis,** the first bishop of the Methodist Episcopal Church in the United States. He was born in Handsworth, Staffordshire, England, in August 1745; d. in Spottsylvania, Va., 31 March 1816. He joined the local ministry of the Methodists at the age of 16, the itinerant ministry six years later, and was sent by John Wesley as missionary to America at the age of 25. In 1772 he was appointed by Wesley general superintendent of the connection in America, the duties of which office he exercised through the entire period of the American Revolution. Until the termination of the war, the Methodists of America had called themselves members of the Church of England, and their ministers laymen. They now considered the political changes of the country as separating them from that Church, and therefore established an organization for themselves. Francis Asbury was constituted the first bishop of the new Church (1784), which office he held till his death. During the 30 years of his episcopal labors he traveled annually from the Androscoggin to the Gulf of Mexico, and from the Atlantic to the Mississippi, ordained not less than 3,000 preachers, and preached about 17,000 sermons. Identified with the religious interests of this country through the two great struggles which have so greatly modified our political and social character, he became eminently American in his sympathies and character, and left the mark of his native enthusiasm and energy upon the ecclesiastical history of the United States.

As'bury Park, N. J., a city and popular summer resort in Monmouth County, on the Atlantic Ocean, six miles south of Long Branch and 40 miles south of New York city. It is on the line of the Pennsylvania R.R. and the Central R.R. of New Jersey. It adjoins Ocean Grove on the north, being separated from it by Wesley Lake. It was founded in 1869, and given a city charter in 1897. It contains many hotels and boarding-houses, attractive summer dwellings, electric lights and street railways, a national bank, etc. It has a property valuation of more than $3,000,000; and is rapidly becoming nearly as popular a winter as a summer resort. Asbury Park and Ocean Grove were originally laid out by members of the Methodist Episcopal Church for camp meetings and other purposes. Pop. (1900) 4,148; in summer, 25,000 and upward.

As'calon, a ruined town of Palestine, on the sea-coast, 40 miles west-southwest of Jerusalem. It was noted during the Crusades, Godfrey de Bouillon gaining here a great victory over the Egyptians in 1099. Its site is now a complete scene of desolation.

Asca'nius, a son of Æneas and Creusa, who accompanied his father to Italy. He supported Æneas in his war with the Latins, and succeeded him in the government of Latium. His descendants ruled over Alba for 420 years. He is known also as Iulus.

As'caris. See ROUND-WORMS; THREAD-WORMS.

Ascend'ants, in law, the opposites to descendants in succession. When a father succeeds his son or an uncle his nephew, etc., the inheritance is said to ascend or to go to ascendants.

Ascen'sion, an isolated volcanic island, near the middle of the South Atlantic Ocean, about lat. 7° 55′ S.; lon. 14° 21′ W.; area about 34 square miles. It belongs to Great Britain; is the sanatorium for the British West African squadron. There are about 400 inhabitants, mainly government employees and their families. Ascension is celebrated for its turtle, which weigh in many cases from 500 to 800 pounds. This island was discovered on Ascension Day, 1502, by the Portuguese, and hence its name; but it was never formally occupied by any nation till Great Britain took possession of it in 1815, after the transportation of Napoleon to St. Helena.

Ascen'sion, Right, a term employed in astronomy in allusion to the position of a star or other heavenly body. Such position is known when we know the right ascension and declination, these terms corresponding respectively to longitude and latitude as applied to the position of places on the globe. Right ascension is measured on the equinoctial or celestial equator, the first point of Aries being taken as the starting-point; and the right ascension of any star is the distance measured eastward along the celestial equator from the first point of Aries to the point where an hour-circle, passing through the star, cuts the equator. The right ascension is easily found by means of the sidereal clock, which, when the first point of Aries passes the meridian, gives the time as 0 hours, 0 minutes, 0 seconds. By noting on the clock the time at which the body is on the meridian, we obtain the right ascension in time, which may be converted into degrees, minutes, and seconds at the rate of one hour to 15°.

Ascen'sion Day, a religious festival of many churches in commemoration of the ascension of the Saviour. It is a movable feast, always falling on the Thursday but one before Whitsuntide. It was first observed about the 4th century.

Asceticism is the exercise of the faculties in moral and religious practices, the application of St. Paul's comparison between an athlete's and a Christian's life (1 Cor. ix. 24, 27). It is negative, when the object of this exercise is to avoid evil, to curb vicious tendencies, moderate excessive passion, and deny the soul and body any indulgence which might become inordinate or unlawful, and whenever it implies active measures against such disorders as gluttony, sloth, anger, pride, and lust, by abstinence, fasting, watching, self-restraint, modesty, and habits conducive to continence. It is positive, when its object is the exercise or training in the virtues which perfect life, and the cultivation of the means most efficacious for this end, such as devout reading, especially of the scripture, meditation, prayer, examination of conscience, exertion, and sacrifice for the good of others, zealous promotion of good enterprises; in a word, anything that can help one to do what is best, constantly, unhesitatingly, and with facility. This is the aim of all true asceticism, whether based on the principles of natural or of positive and revealed law. This aim, as well as many of the means above numerated, is found to some extent in Pagan and Jewish, as well as in Christian asceticism. The latter employs additional means of inculcating and developing the habit of virtue, such as the religious life, divine worship, and in particular the sacramental system of the Church. Asceticism has some part in every rightly regulated life, even in one based on purely ethical principles; but in Christian life it is most systematic and far-reaching. The whole Christian economy depends on self-denial and the active pursuit of virtue according to fixed principles. Every sincere Christian is, accordingly, an ascetic, some are professedly so, men and women, whether in the conventual cloister or domestic circle, who strive to acquire by daily practice habits of virtue, and to advance in holiness. Naturally counsel and direction are needed in a matter so difficult, and it is for want of due attention to these that asceticism is often misunderstood, and is regarded by some as grotesque, a shield for certain excesses and extravagances, associated often with the external observances of communities like the Essenes, with the singularities of some hermits and anchorites, the frenzy of fanatics like the Flagellants, the exclusiveness of the Brahmins, the ablutions of the Mohammedan, the dream of men like those composing the Brook Farm Community. To appreciate asceticism in its normal exercise, one must study it in the examples of men and women noted for its exercise, or in the books whose guidance they followed, in works of the great ascetical and sermon writers, but chiefly in scripture, and in the life of Christ and of persons distinguished for holiness. See Kempis, 'Imitation of Christ'; Rodriguez, 'Christian Perfection'; Scaramelli, 'Ascetical Directory.'

Ascet'ics, a name anciently given to those Christians who devoted themselves to severe exercises of piety, and strove to distinguish themselves from the world by abstinence from sensual enjoyments and by voluntary penances. Hence those writings which teach the spiritual exercises of piety are termed ascetic writings. Even before Christ, and in the time of the early Christian Church, there were similar ascetics among the Jews, such as the Essenes, also among the philosophers of Greece, and in particular among the Platonics. The expression is borrowed from the Greek word *askēsis* (exercise), used to signify the spare diet of the athletæ, who, to prepare themselves for their combats abstained from many indulgences.

Asch, äsh, a manufacturing town in the extreme northwest corner of Bohemia. It contains a large Protestant and a newly-erected Roman Catholic Church, a real-school, schools of design, weaving, etc. The inhabitants are mainly employed in cotton, woolen, and silk manufacture, bleachfields, and dye-works. Pop. (1900) 18,700.

Aschaffenburg, a-shä'fĕn-bürg, a town of Bavaria, 26 miles east-southeast of Frankfort. The chief edifice is castle of Johannisberg, built in 1605–14. There is also the Pompeianum, an edifice built by King Louis of Bavaria, in imitation of the Casa del questore (commonly called the Castor and Pollux House) at Pompeii. The principal industries are the manufactures of colored paper, tobacco, and liquors. There are also large breweries, and an extensive trade is done in wine and timber. Aschaffenburg long belonged to the archbishops of Mainz. Pop. (1900) 18,091.

Ascham, ăs'kăm, **Roger,** an English scholar: b. Kirby, Wiske, Yorkshire, 1515; d. London, 30 Dec. 1568. While still a child, he was taken into the family of Sir Anthony Wingfield and educated with the latter's children. He made rapid progress in English and classical studies, and was taught archery by Sir Anthony himself. The same generous patron sent him in 1530 to St. John's College, Cambridge, where he read nearly all extant Latin literature, acquiring an elegant Latin style that proved most useful to him later, and developed an especial aptitude for Greek, which he taught to students younger than himself. Besides this, he paid some attention to mathematics, became an accomplished musician, and acquired remarkable skill in penmanship. He received his B.A. degree in February 1533-4, and became a Fellow of his college. His reputation for Greek learning soon brought him many pupils, several of whom later rose to distinction, and students from other colleges attended his lectures. In five years, he afterward said, Sophocles and Euripides had become at his college as familiar as Plautus had been previously, and Demosthenes was as much discussed as Cicero. The beauty of his handwriting and the purity of his Latin led to his being employed to write the official letters of the university. He took an active part in the controversy as to the correct mode of pronouncing Greek, opposing Sir John Cheke's system, but later adopting it. In 1543-4 he wrote his famous treatise on archery, 'Toxophilus,' and in person presented a copy of it to Henry VIII., who so approved of the work that he gave the author an annual pension of £10, which was renewed by Edward VI., whose Latin secretary Ascham became. In 1548 he was appointed tutor to Princess Elizabeth. He read with her all 'Cicero,' the greater part of 'Livy,' the 'New Testament,' in Greek, 'Isocrates,' 'Sophocles,' and portions of 'Cyprian' and 'Melancthon.' Two years later he was nominated secretary to Sir Richard Morysin, ambassador to the Emperor Charles V. Their headquarters were at Augsburg, but Ascham made trips to Louvain, Halle, Innspruck, Venice, and Brussels, visiting famous teachers and scholars. He lived on excellent terms with Sir Richard, reading Greek with him five days in the week. The death of Edward caused the recall of the embassy in 1553. Ascham became Latin secretary to Queen Mary and gave proof of his industry by writing for her within three days 47 letters to persons of high rank, of whom cardinals were the lowest in degree. With the accession of Elizabeth, he was continued in his offices and became in addition private tutor to the queen, reading several hours a day with her in the learned languages. She bestowed on him the prebend of Wetwang in York Cathedral 5 Oct. 1559. His last years were filled with anxiety and care due to domestic afflictions and pecuniary embarrassment. Between 1563 and his death he found relief in the composition of his best known work, 'The Scholemaster,' of which he completed two books. The first is a general discussion of education with arguments in favor of inducing a child to study by gentleness rather than by force. The second is an exposition of his famous method of teaching Latin, by means of "double translation," etc., a method which has received high praise from all subsequent writers on the theory and methods of education. When Queen Elizabeth heard of Ascham's death, she is said to have exclaimed that she would rather have cast £10,000 into the sea than to have lost her tutor, Ascham. Scholars in England and on the Continent mourned for him, and expressed their grief in stately Latin verses. In English literature Ascham has a secure place on account of the strength and vigor of his English prose, highly Latinized though it was in construction and vocabulary. In an age when serious literary composition in English was cultivated but little, and regarded less, the famous words in his dedication of 'Toxophilus' to Henry VIII. sounded a noble and patriotic note. "Althoughe to have written this boke either in Latin or Greeke . . . had been more easier and fit for mi trade in study, yet nevertheless, I supposinge it no point of honestie, that mi commodite should stop and hinder ani parte either of the pleasure or profite of manie, have written this Englishe matter in the Englishe tongue, for Englishe men." His style is without the tricks that Lyby introduced, and has an easy flow and straightforwardness.

Bibliography.— By far the best edition of Ascham's writings is 'The Whole Works of Roger Ascham . . . with a Life by Dr. J. A. Giles' (3 vols. in 4 parts, Lond. 1864-5). This edition includes 295 Latin and English letters, many printed for the first time. 'Toxophilus' was first published in 1545; other editions appeared in 1571, 1589, 1788, 1821, 1865 (by J. A. Giles), 1868 (by E. Arber). 'The Scholemaster' was first issued 1570, and was followed by editions in 1571, 1572, 1573, 1579, 1583, 1589, 1711, 1743. Prof. J. E. B. Mayor published best modern edition in 1863, and E. Arber reprinted the first edition in 1870. The best exposition of Ascham's educational system is in R. H. Quick's 'Essays on Educational Reformers' (1868). *Cf.* also article by Sidney Lee in 'Dictionary of National Biography.'

Aschersleben, ä'sher-lā'bĕn, a town of Prussian Saxony, in the district of Magdeburg. It is walled and entered by five gates, and contains several churches, a synagogue, and a realschool of the first class. There are manufactures of woolen goods, paper, sugar, artificial manures, earthenware, etc. Among several interesting ruins in the vicinity is the old castle of Askanien, the cradle of the house of Anhalt. Pop. (1900) 27,245.

Ascid'ian, a marine animal, so called from *Ascidia*, a genus of *Tunicata*. Ascidians were once regarded as mollusks, and afterward as worms, but when their embryology and early stages were studied and it was found that they passed through a tadpole-like stage, in which the tail is supported by a notochord, and that in other respects they approached the vertebrates, they were placed with the vertebrates in the group *Chordata*. The simple ascidians attain to a large size, *A. callosa* being about two inches in diameter, quite round, and in shape and color much like a potato. The "sea-peach" (*Cynthia pyriformis*) is of the size and general shape of a peach, with its rich bloom and reddish tints. It is common at a depth of 10 to 50 fathoms on both sides of the north Atlantic. While other forms, as *Boltenia*, are stalked and fixed to the bottom, certain pelagic forms, as *Pyrosoma*

and *Salpa* (q.v.), are free-swimming. The compound ascidians, such as *Amarœcium*, grow in white or reddish masses on sea-weeds, rocks, shells, etc., the individual animals being minute. The interesting form *Perophora* grows in bunches on piles and wharves on the southern coast of New England; it is perfectly transparent, so that the heart and circulation of the blood can readily be observed under the microscope. The heart is a straight tube, open at each end; after beating for a number of times, throwing the blood with its corpuscles in one direction, the beatings or contractions are regularly reversed, and the blood forced in an opposite direction. For a general account of the anatomy, development, and metamorphoses of these animals, see TUNICATA.

Ascle'piada'ceæ, a natural order of more than 200 genera and 2,000 species of dicotyledonous herbs and shrubs, most of them with milky juice and many of them twining. The species are widely distributed in the temperate and tropical zones of both hemispheres and are especially abundant in Africa. They differ greatly in their characteristics and uses; some, like *Stephanotis floribunda,* are delightfully fragrant; others, like *Stapelia gigantea,* carrion flower, are repellantly odoriferous. Some species yield a fibre from their stems or their pods; some are used in medicine; others are planted for ornament. They are characterized by opposite or whorled, seldom scattered, entire leaves without stipules; umbels of symmetrical flowers, without calyx and with a five-parted corolla with often reflexed lobes; five stamens attached to the corolla and more or less united around the stigma; pollen grains more or less coherent; the ovary composed of two carpels; style short; stigma discoid; fruit a follicle or pod; seed flattened, with long silky hairs, which buoy it up in the air for dispersal; cotyledons flat. In the United States Asclepias (q.v.), or milkweed, is the principal genus. The more important genera are grouped as follows: TYLOPHOREÆ, *Marsdinia, Stephanotis, Cereopegia, Stephelia, Hoya;* GONOGLOBÆ, *Gonoglobus;* PERIPLOCHÆ, *Periplocha, Streptocaulon;* ASCLEPIADÆ, *Asclepias, Cynanchum, Vincetoxicum.*

Asclepiades, ăs'kle-pī'a-dēz, the name of several ancient Greek writers — poets, grammarians, etc.— of whom little is known, as well as of several physicians, the most celebrated of whom was Asclepiades, of Bithynia, who acquired considerable repute at Rome about the beginning of the 1st century B.C.

Ascle'pias, milkweed, silkweed, swallow wort, the type genus of about 125 species of the natural order *Asclepiadaceæ* (q.v.), the species of which are mostly North American erect perennial weeds with thick, deep roots common in pastures and waste places. Some furnish a fibre strong enough for ropes, and the silky down attached to which is useless for spinning, is often used for stuffing pillows, etc. The young shoots of some species are occasionally cooked like asparagus, which they are said to resemble somewhat. *A. tuberosa,* butterfly-weed, pleurisy root, common in dry banks and fields from Ohio to Georgia, is very showy and seems to deserve a place in the flower-garden. Other well-known American species are *A. rubra, A. purpurascens, A. syriaca,* etc. The few species cultivated for ornament in America are mostly foreign. The genus is named in honor of the Greek god Asclepine, since some of the species are reputed carminatives, sudorifics, and expectorants. Medicinally the milkweeds are of secondary value only. They are irritants, and cause nausea, vomiting, and diarrhœa. They also cause diuresis and diaphoresis, but their exact action is in need of investigation. The eclectic school have been the chief investigators.

Ascoli, äs'kō-lē, or **Ascoli Piceno,** äs'kō-lē pēchā'nō (the ancient Asculum), an Italian town, 90 miles northeast of Rome. The town, one of the most ancient in Italy, is well built, and contains many handsome edifices and noble mansions, and the remains of an ancient theatre, temples, etc. It has manufactories of woolen cloths, leather, hats, cream of tartar, china-ware, sealing-wax, paper, and glass. It has an active trade, and its port, at the mouth of the river Tronto, is much frequented by coasting vessels. Pop. (1901) 28,882.

Ascoli Satriano, äs'kō-lē sä'tre-ä'nō (anc. *Ascŭlum Apŭlum*), a town of southern Italy, 20 miles south of Foggia. Pop. (1901) 8,550.

As'comyce'tes, a large and important group of fungi, so called from their spores being contained in asci or sacs. This group includes mildews, rusts, smuts, the truffle, the morel, and (according to Schwendener and other authorities) the lichens. See Engler and Prantl, 'Die Natürlichen Pflanzenfamilien.' See FUNGI.

Asco'nius (QUINTUS A. PEDIANUS), a Roman historian of the 1st century A.D., who wrote a life of Sallust, a reply to the critics of Virgil, and valuable commentaries to Cicero's orations, some of which are extant.

As'cot, a celebrated English race-course near the southwest extremity of the Windsor park. The annual races, which take place in the second week in June, are attended by the fashionable and sporting public. From the accounts of the Master of Horse for the year 1712, it would appear that they were instituted, not in 1727, as is commonly supposed, but by Queen Anne on 6 Aug. 1711.

Ascutney, ăs-kŭt'nĭ, an isolated granitic mountain on the boundary between Windsor and Weathersfield, Vt. Its summit is 3,320 feet above tide-water; and from it is presented an extensive and beautiful prospect of the valley of the Connecticut.

As'dood, or **Asdoud,** a seaport of Palestine, on the Mediterranean, 35 miles west of Jerusalem. It was the Ashdod of scripture, one of the five confederate cities of the Philistines, and one of the seats of the worship of Dagon (1 Sam. v. 5). It occupied a commanding position on the high road from Palestine to Egypt, and was never subdued by the Israelites. It sustained against Psammetichus a siege of 29 years; was destroyed by the Maccabees, and restored by the Romans. It is now an insignificant village, from which the sea is constantly receding.

Aselli, a-sĕl'lee, **Gasparo,** a famous Italian physician: b. Cremona about 1580; d. 1626. He was professor of anatomy and surgery at Padua, and in 1622 discovered the lacteal vessels, which he seems, however, never to have

understood or described with complete accuracy. He left a treatise, 'De Lactibus' (1627).

Asel'lus, a fresh-water isopod crustacean, allied to the wood-lice (q.v.), common in ponds and standing water, under sticks and stones, and in open caves. These crustaceans differ from the common pill bugs of the land in having a pair of rather long forked two-jointed caudal appendages and antennæ of the second pair reaching to the telson. The body is broad and flat, with a broad shield-like telson, formed by the fusion of the last abdominal segments. There are six pairs of legs arising from the middle region of the body between the head and telson. The female carries her eggs under her breast, behind the head. Respiration is carried on by several pairs of broad, gill-like sacks appended to the broad, flat abdominal legs. Blind individuals occur in caves, which are allied to the true blind *Asellus cæcidotæa.*

Asen, ä'sĕn, in northern mythology, the most powerful of the gods. They included 12 gods and the same number of goddesses, among the most renowned of whom were Odin, Thor, Baldur, Freyr, Frigga, Freyja, Idunna, Eira, and Saga. Their dwelling-place was Asgard. Though this worship was native only to the tribes of Scandinavia, its influence extended throughout ancient Germany, and may still be traced in many German proper names. Thus the German names of the days of the week, which through the Saxons became incorporated into the English language, are derived from this mythology. (See ASGARD.) Asen was also the name of several mediæval czars of Bulgaria.

As'enath, the daughter of Potipherah, priest of On, and the wife of Joseph (Gen. xli. 45, 50).

Asepsis. See ANTISEPTICS.

Asex'ual Generation. See PARTHENOGENESIS.

Asgard, ăs'gärd, the home of the Æsir, or Asen, and the Olympus of northern mythology. The city of Asgard is fabled to have been built in the middle of Ida's plain, the very centre of the universe. Here the Æsir erected a court for themselves with seats for 12 and one high seat for Odin, the All-father, and also a lofty abode for the goddesses, called Vingolf. They worked diligently, played at games, were rich in gold and all precious things, and happy, till three maidens from Jotunheim, the giants' world, crossed Ida's plain and entered Asaheim, when corruption spread among its inmates. Asgard had many mansions, the largest and noblest of which was Gladsheim; while another, not so spacious, but the fairest of all and brighter than the sun, was called Gimli. See SCANDINAVIAN MYTHOLOGY.

Asgill, ăs'gĭl, **John,** an eccentric English writer: b. Hanly Castle, 1659; d. 1738. He was bred to the law, and gained considerable reputation, not only by skill in his profession, but from his pamphlet declaring that man might pass into eternal life without dying. In 1703 he took his seat in the Irish Parliament, but was dismissed after four days on account of his so-called blasphemous pamphlet. In 1705 he sat in the English Parliament for Bramber; but in 1707 he was expelled, nominally on account of his unlucky pamphlet, but really perhaps because of his debts. The remainder of his life he spent in the Fleet and King's Bench prisons, in one of which he died. He wrote a number of pamphlets on the Pretender and on the Hanoverian succession.

Ash (*Fraxinus*), a genus of about 50 species of hardy, ornamental trees of the natural order *Oleaceæ,* natives mainly of North America, Europe, and western Asia. The species are prized for street and park planting for which their usually tall pyramidal or broad-topped habits and light, green foliage, which turns yellow or purple in autumn but which falls early, makes them specially attractive. From the elegance of their forms several species, notably the first mentioned below, have been called the Venus of the forest; the oak being the Hercules. The leaves are rather large opposite, pinnate, and deciduous; the flowers greenish or whitish in panicles, appearing either before, with, or after the leaves; the fruits are rather small samaras. Since grass and other plants do not grow well in the immediate vicinity of the ash it is not a good lawn species. The common ash (*Fraxinus excelsior*), a native of Europe and western Asia, found in its perfection upon loamy soil, often attains a height of 120 or even 150 feet. It also thrives in exposed and elevated situations better than many other trees. Its naked flowers appear long before the leaves, which drop early in the autumn, but during the summer are very ornamental. Its leaflets are sessile and serrated toothed. Its tough, hard, white wood makes excellent fuel and is highly valued for turning (for carriage wheels especially) when the tree has grown rapidly, since the toughness is then very great. It is then particularly valuable for carriage shafts, ladders, handles of agricultural tools, such as rakes, pitchforks, and hoes, where pliability, toughness, and lightness are essential. For such uses its only important rival in America is the hickory. When gnarled, as it occasionally is, it is prepared like "curly" maple for cabinet work and furniture, specially fine-grained specimens being used as veneer. The bark is used to some extent in leather tanning. A large number of cultivated varieties have been produced, among which the most remarkable are: *Monophylla* (erroneously raised by some botanists to the rank of a species), with simple instead of compound leaves or with only one or two small leaflets at the base of the main leaf-blade; *albo marginata,* the leaflets of which are bordered with white; *albo-variegata,* with mottled white and green leaflets; *aurea,* yellow branched; *aurea-pendula,* drooping yellow branches; *pendula,* one of the best weeping trees; *crispa,* with curled and twisted very dark green leaves. The American or white ash (*F. americana*), a very variable species common from New Brunswick to Florida and westward to Minnesota and Texas, but rare south of New Jersey, attains about the same size as the preceding species, but has lighter bark and leaves. The leaflets have short stalks and are entire. In rich, moist, dense woods the trunks often attain a height of 40 feet without a branch, thus furnishing valuable timber, which is used for the same purposes as that of the preceding species. There are many varieties which more or less resemble those of the common ash. The black or water ash (*F. nigra*), common in swamps and upon stream

banks from Nova Scotia to Minnesota and southward to Missouri and Virginia, often attains a height of 80 feet. Its wood is softer than that of the preceding, but, being tough and easily separable longitudinally into layers, is largely used for veneer, baskets, barrel staves and hoops. The name *F. sambucifolia,* by which this species is sometimes called, was given it because the bruised leaves smell like those of elder. The red ash (*F. pubescens* or *F. pennsylvanica*) is common in low ground from maritime Canada to Florida, being especially abundant in the swamps of Pennsylvania, Maryland, and Virginia. It is rare west of Ohio, though found as far west as Dakota and Minnesota. It resembles the American ash in uses and in general appearance. The interior of the outer bark of the branches is cinnamon color or red when fresh. The blue ash (*F. quadrangulata*), common in rich, dry, or moist woods from Michigan and Minnesota to Tennessee and Arkansas, and especially abundant in Ohio and Kentucky, attains a height of 80 to 120 feet. Its branches are more or less four-angled, hence the specific name, and the membranes which give the smaller branches this form are specially noticeable on the young shoots. The inner bark yields a blue color when steeped in water, hence the common name. The green ash (*F. viridis*), a species very widely distributed over Canada and the United States from ocean to ocean, is so called from the brilliant green of its young shoots. It is extensively planted to form windbreaks in Minnesota and the Dakotas on account of its extreme hardiness and because it is easily propagated by seeds and also because it grows very rapidly. It is less valued for its wood than the white ash, but is useful for fuel. The Carolina or water ash (*F. caroliniana,* also referred variously to *F. platicarpa* and *F. americana*) seldom exceeds 40 feet in height, but is noted for its very large leaflets. It is distributed from Virginia to Florida and westward to Arkansas and Texas, being most plentiful in swamps, along water courses and in damp, rich woods. Its wood is used like that of the white ash. *F. cuspidata,* a native of the southwestern United States and northern Mexico, is a shrub or small tree which seldom exceeds 20 feet in height, and on account of its conspicuous panicles of fragrant flowers is often planted in temperate climates for ornamental purposes. *F. velutina,* also sometimes referred to *F. pistaciæfolia,* another species of the same region, seldom attains a height of 50 feet, and not being hardy is confined to southern planting. The manna or flowering ash (*F. Ornus* or *Ornus europæa*), a native of southern Europe and western Asia, is a small tree 25 feet tall which resembles the common ash. It furnishes manna (q.v.), as does also *F. rotundifolia,* which by some botanists is considered a variety of *F. Ornus.* It is a native of Greece. Many other species are of botanical, economic, or ornamental interest, but probably none of as much importance as the species mentioned. The mountain ash (q.v.), a member of the natural order *Rosaceæ,* obtains its name from its ash-like leaves.

Consult: Nicholson, 'Dictionary of Gardening' (1888); Bailey and Miller, 'Cyclopædia of American Horticulture' (1900–2).

Ash, or Ash'es, the fixed residue obtained by burning any part of an organized substance in air. Ash usually contains the following, or some of the following, metallic and non-metallic elements:

Metals	Non-metals
Potassium	Chlorine
Sodium	Bromine
Calcium	Iodine
Barium	Phosphorus
Iron	Sulphur
Manganese	Silicon
Aluminum	Carbon
Copper	
Zinc	

These substances are combined in various forms in the living body of the plant or animal. They are derived from the soil in the case of plants, and chiefly from plants in the case of animals. Different parts of the animal or vegetable frame are characterized by differences in the ash which they leave when burned; thus ash of bones consists largely of phosphate of calcium; the animal fluids and the juices of plants contain chlorid of sodium; sea-plants leave an ash rich in alkaline carbonates and also characterized by the presence of bromids and iodids of the alkalies. (See BARILLA; KELP.) Many grasses contain large quantities of silica, which appears in the ash of these plants. An examination of the ash of plants often leads to important conclusions as to the most suitable manure to employ for enriching the soil in which the plants are to be grown.

Ashes.— The non-volatile, inorganic portion of an animal or vegetable substance left behind after incineration. Ashes consist of the most part of carbonates, sulphates, sulphids, silicates and phosphates of potassium, sodium, calcium, magnesium, manganese, and iron, with occasional admixture of unusual elements such as aluminum. In certain seaweeds iodin is a prominent constituent of the ash, and silica occurs in many rushes. The solid matters taken up by plants are not absorbed in anything like the proportions in which they occur in the soil whence they are derived. This is well illustrated by analyses of the ashes of different plants, growing side by side in the same soil. Thus Kerner gives four such analyses, made on the ashes of (1) the water-soldier (*Stratitoes aloides*); (2) the white water-lily (*Nymphæa alba*); (3) a stonewort (*Chara fœtida*), and (4) a reed (*Phragmites communis*). The results, so far as potash, soda, lime, and silica are concerned, are as follows:

PERCENTAGE COMPOSITION OF ASH.

	Water soldier	Water lily	Stonewort	Reed
Potash	30.8	14.4	0.2	8.6
Soda	2.7	29.7	0.1	0.4
Lime	10.7	18.9	54.8	5.9
Silicic Acid	1.8	0 5	0.3	71.5

These four plants grew close together and the soil from which they drew their supplies was identical, so far as could be discovered. The stonewort, it will be seen, contained a very large quantity of lime, and barely a trace of potash, soda, or silica; while nearly three quarters of the ash of the reed consisted of silica, and there

ASH (Fraxinus excelsior).

1, 2. The unfolding of the bud. 3. A shoot in flower. 4, 5, 6. Andrcgynous flower, from different sides. 7. The stamen, exposed with two anthers on their filament. 8. The pistil. 9. The seed-pod, exhibiting the hanging seeds. 10. Section of the seed-pod. 11. Spray of hanging fruit. 12. Fruit laid open, exposing seed. 13. The two lobes of the seed, showing inner and outer side. 14. Seedling plant.

was less than one ninth as much lime as was found in the stonewort. If we pass from the consideration of different plants growing in the same soil to that of the same plant growing in different soils, the results are equally surprising. Thus Kerner gives analyses of the ash obtained from the foliage and branches of the yew tree (*Taxus baccata*), the specimens analyzed being taken from soils rich in serpentine, limestone, and gneiss, respectively. The results are presented in the accompanying table. It will be seen that there are some slight differences in composition, but when the wide difference in the soils is taken into account it is remarkable that the proportions are so nearly alike.

Substance Found	Nature of Soil		
	Serpentine	Limestone	Gneiss
Silicic Acid	3.9	3.6	3.7
Sulphuric Acid	1.9	1.6	1.9
Phosphoric Acid	8.3	5.5	4.2
Iron Oxid	2.1	1.7	0.6
Lime and Magnesia	38.8	41.2	36.3
Potash	28.6	21.8	27.6
Carbonic Acid	14.1	23.1	24.4

One feature that was prominent in the analyses of the yew-tree ash has been purposely obscured in the table by counting the lime and magnesia *together*. It appears that when a plant needs a certain substance for its growth it will sometimes make use of another substance whose chemical properties are closely similar, provided the more desirable one cannot be had in sufficient quantities. Thus the ash of the yew-trees growing over limestone contained 36.1 per cent of lime and 5.1 per cent of magnesia; and that of the trees growing over gneiss contained 30.6 per cent of lime and 5.7 per cent of magnesia. The serpentine soil, however, was much poorer in lime than either of the others,— serpentine being composed almost entirely of magnesium, silicon, and oxygen,— and the trees growing upon this soil, being unable to obtain the necessary quantity of lime, accepted, in the place of the lime, an equal weight of magnesia, which strongly resembles lime in its chemical properties; the observed quantity of lime in these trees being only 16.1 per cent, while magnesia was present to the extent of 22.7 per cent. The ashes of plants show that in certain cases the plants from which they are obtained possess a wonderful power of collecting large amounts of some particular substance, even when this substance is present in the soil or water in which they are growing in such minute quantities that it can barely be detected by the most delicate chemical tests. For example, the sea-weeds of the North Sea are so rich in iodin that their ashes formed the chief supply of this substance for years,— in fact, until the extensive South American deposits of sodium iodid were discovered. It would naturally be inferred that the North Sea contains considerable quantities of soluble iodids; but the fact is, that no trace of iodin or of iodids has yet been detected in it, by the most delicate tests. Wood ashes have long been used as a source of potash, this substance being readily obtained from them by mere leaching with water. The greater part of the potash of commerce is now obtained from other sources, but the leaching process is still in use in country places where wood ashes are plentiful, the potash so obtained being chiefly used for the manufacture of soap. Wood ashes are also valuable for fertilizing purposes, on account of the potash and phosphorus they contain.

Ash'-fly, the gall-fly of the oak (*Cynips quercifolia*). See GALLS; GALL-FLY.

Ash'-leaved' Ma'ple. See BOX ELDER.

Ash'-Wednesday, the first day of Lent. The name is derived from the ancient custom of putting ashes upon the head as a symbol of humble repentance for sin. In the Roman Catholic Church it is part of the religious service on this day for the priest to put ashes on the forehead of each worshipper while kneeling at the altar rails. In the English Church and in the American Episcopal Church the day is observed with especial solemnity as the opening of the penitential season, and also in the Unitarian "King's Chapel," in Boston, Mass.

Ashantee, a-shän'tē, a negro kingdom of western Africa and practically a part of the British colony of the Gold Coast. Its boundaries cannot be stated with any definiteness, but its area may be roughly estimated at 10,000 square miles. It is in general hilly and is largely covered with forests. It is well watered and extremely fertile, but the climate is unhealthy. Among the trees are the baobab, palms, and cotton trees. The crops are chiefly rice, corn, sugar-cane, and yams, the last forming the staple vegetable food of the natives. The domestic animals are cattle, horses of small size, goats, and a species of hairy sheep. The larger wild animals are the elephant, rhinoceros, buffalo, lion, hippopotamus, etc. Birds are numerous and crocodiles and other reptiles abound. Gold is obtained, being found either in the form of dust or in nuggets. The Ashantees long made themselves well known as being warlike and ferocious, with a love of shedding human blood amounting to a passion. Human teeth and jawbones were worn as personal ornaments, and human sacrifices used to be frequent. On the death of a king or chief enormous numbers of victims were slaughtered with circumstances of revolting cruelty, and there were regularly recurring periods, at intervals of 18 or 24 days, called the great and little *adai*, when human sacrifices were made. Notwithstanding this there exist among the Ashantees certain of the arts of civilization. They excel in the manufacture of cotton cloths and in the fabrication of articles in gold; they make good earthenware, tan leather, and make sword-blades of superior workmanship. The native government is a monarchy. The chief town is Coomassie or Kumasi. The British first came in contact with the Ashantees in 1807, when a treaty was concluded by the governor of Cape Coast with the king of Ashantee, acknowledging the sovereignty of the latter by right of conquest over the coast, including Cape Coast Castle. In 1823 war was proclaimed by the Ashantees against the British, and they succeeded in the following year in defeating a small body of troops led by the governor, who perished with almost all his officers; but in 1826 the Ashantees were completely defeated near Accra. At the close of another war, in 1831, the river Prah was fixed as the bound-

ary between the Ashantee kingdom and the states protected by Great Britain, but the Ashantees soon began to interfere beyond the boundary. Early in 1873 the Ashantees again invaded the territory protected by Great Britain, and Gen. Wolseley (subsequently Viscount Wolseley) was now sent against them. The Ashantee general Amanquantia had concentrated his troops, 20,000 strong, at Amoaful, 20 miles from Coomassie. The British general led to the attack 1,481 English and 708 native troops, whom he formed into a square. The battle began on 31 January, on which day Amoaful was taken. The British continued to advance fighting, the enemy at the same time attempting to break in upon their rear by attacking the troops left at Fommanah. On the 4th Coomassie was entered. The loss of the British in killed and wounded was 300, and a large number ultimately succumbed to the climate. As the king refused to enter Coomassie to sign a treaty, the British set fire to the town and began their return march on the 6th. The treaty signed soon after stipulated that the king of Ashantee should renounce his claims to the protectorate over the allies of Great Britain; that free trade and open communication should be established with the coast, and that the king should pay an indemnity of 50,000 ounces of gold. The last condition was not faithfully observed, but the result of the war was greatly to weaken the power of the Ashantees. The conduct of King Prempeh, a successor of King Koffee, led to the dispatch of another British expedition, which in 1896 entered Coomassie without resistance, and received the abject submission of the king, who was taken and sent into banishment. A British resident has since been stationed in the country, which is now a British protectorate, subordinate to the governor of the Gold Coast, and will no longer be the scene of human sacrifices and slave trading. In June 1898 an agreement was arrived at between Great Britain and France with regard to the boundaries between their respective territories here. The population of Ashantee is estimated at from 1,000,000 to 3,000,000.

Ash'burner, Charles Albert, an American geologist: b. Philadelphia, 9 Feb. 1854; d. Pittsburg, 24 Dec. 1889. He graduated at the head of his class at the University of Pennsylvania, and was appointed assistant State geologist in 1875. He originated a method of surveying and representing the geology of the anthracite coal fields which received the approbation of mining engineers throughout the world. He was also an accepted authority on the natural-gas fields. In 1886 he entered private practice as an expert and became closely associated with the Westinghouse interests. He prepared over 20 of the Pennsylvania State geological survey reports, and contributed to scientific and technical journals.

Ash'burnham, Sir Cromer, an English military officer: b. 1831. He served with distinction in the Indian Mutiny campaign, Afghanistan campaign, the Boer war (1881), the Egyptian, and eastern Sudan campaigns; and was subsequently governor of Suakim.

Ash'burton, Alexander Baring, Lord, an English statesman and financier: b. London, 27 Oct. 1774; d. 13 May 1848. He was the second son of Sir Francis Baring, and the affairs of the famous mercantile house established by his father kept him employed in Canada and the United States for many years. In 1810 he became the head of the house of Baring Brothers, and in 1812 sat in Parliament for Taunton. He was created Baron Ashburton in 1835. He was appointed special ambassador to the United States in 1842 to settle the Northwestern boundary question and other matters in dispute between England and America. A street in Boston, known as Ashburton Place, was named in his honor.

Ash'burton River, a stream in western Australia flowing 400 miles and emptying into the Indian Ocean, lat. 22° S.; lon. 115° W.

Ash'burton Trea'ty, a treaty concluded at Washington in August 1842 by Alexander Baring, Lord Ashburton, and the President of the United States. It defined the boundaries between the United States and Canada.

Ash'by, Turner, an American soldier: b. 1824; d. June 1862. He entered the Confederate army in 1861 and became a brigadier-general. He was especially distinguished for his gallantry. He was killed in a skirmish at Harrisburg, Va.

Ashby-Sterry, Joseph, a well known English writer on the staff of the *Daily Graphic.* He is novelist and poet, as well as journalist, and among his published books are: 'Nutshell Novels' (1890); 'The Lazy Minstrel,' a collection of brilliant verse (1892); 'Naughty Girl, a Story of 1893' (1893); 'A Tale of the Thames in Verse' (1896); 'The Bystander, or Leaves for the Lazy' (1900).

Ashby-de-la-Zouche, ăsh'bĭ-dĕ-la-zooch', a market town in Leicestershire, England, on the borders of Derbyshire, 17 miles northwest of Leicester. It has wide, well-paved streets, and its parish church of Saint Helen is a handsome building with stained-glass windows, carvings, and monuments. The Ivanhoe baths attract visitors, the waters being beneficial for some ailments. The ruins of Ashby Castle, well known to readers of 'Ivanhoe,' which received Mary Queen of Scots as a prisoner, are still visible. Pop. (1901) 4,700.

Ash'dod. See Asdood.

Ashe, ăsh, **John,** an American soldier: b. in North Carolina, 1720; d. 24 Oct. 1781. He was a member of the first Provincial Congress and served in the American Revolution as a brigadier-general of North Carolina troops. Asheville, N. C., was called in his honor.

Ash'er, the name of the eighth son of Jacob. He founded the tribe called after him, which occupied a fertile territory in Palestine along the coast between Carmel and Lebanon.

Asheville, ăsh'vĭl, N. C., a city and county-seat of Buncombe County, on the Southern R.R., near the French Broad River; 275 miles west of Raleigh. It is in a tobacco-growing region; has manufactories of cotton goods, shoes, ice, tobacco, and flour; and is widely famed as a winter and summer resort. The city is 2,350 feet above the level of the sea and is surrounded by impressive mountain scenery. It has the Asheville College for Young Women, Bingham Military School, Asheville School for Boys, Normal College and Collegiate Institute for Young

Women, Home Industrial School for Girls, Asheville Farm School for Boys, Industrial School for Colored Youth, an auditorium centrally situated seating 2,000, and free to conventions, weather bureau, three national banks, and nearly 50 hotels and boarding-houses. It has modern sewerage, electric light and gas plants, a water supply by 17 miles of pipe line from trout streams on the water shed of Mt. Mitchell, and an electric street car system with a trolley road to Sunset Mountains. In the suburbs are the grand estate of Biltmore, established by George Vanderbilt of New York city; one of the finest botanical gardens in the world; Pisgah forest, a hunting preserve of 84,000 acres; Riverside Parks; and Mount Beaumont, 2,800 feet high. Pop. (1900) 14,694.

Ashe'ville College, a non-sectarian educational institution for women, in Asheville, N. C. It was organized in 1842, and at the end of 1899 had 17 professors, 135 students, and grounds and buildings valued at $100,000.

Ash'ford, a market-town in Kent, England, pleasantly situated on the river Stour. There are corn and cattle markets, and the Southeastern Railway Company have their principal locomotive and carriage establishments here. Pop. (1901) 12,808.

Ash'hurst, John, an American surgeon: b. 1839; d. 1900. He was graduated at the University of Pennsylvania in 1857; served as an army surgeon in the Civil War; became surgeon of several Philadelphia hospitals after his return; and was made president of the College of Physicians in Philadelphia in 1898. He held surgical chairs in the University of Pennsylvania; was a member of the principal medical and surgical associations of the country; and besides many individual publications edited the 'International Encyclopædia of Surgery' (1881–1886); and 'Lippincott's New Medical Dictionary.' He was the author of 'Injuries of the Spine' (1867); and 'Principles and Practice of Surgery' (1871).

Ashikaga, ä'she-kä'gä, a town in Japan, 17 miles by rail from Tokyo. From the 9th to the 17th century it was of much importance as a seat of learning. It is now noted for its trade in silk and cotton. Pop. (1898) 21,348.

Ash'kelon. See ASCALON.

Ash'land, Ky., a city of Boyd County, situated on the Ohio River; on the Chesapeake & Ohio, Norfolk & Western, and other railroads. It was chartered as a city in 1870. Its manufactures include cut and wire nails, steel billets, sheet steel, leather furniture, etc., and it is a shipping point for iron ore and coal. Pop. (1900) 6,800.

Ash'land, Ky., an estate in the suburbs of Lexington, famous as the home of Henry Clay. It consists of about 600 acres, 200 of which form a park similar to the large private parks of England. The house in which Mr. Clay lived was a plain structure, two stories in height. After his death the property passed by public sale into the hands of his eldest son, James B. Clay, who took down the old house and rebuilt it.

Ash'land, Ohio, a town and county-seat of Ashland County; on the Erie R.R., 65 miles southwest of Cleveland. It has important manufactures, large trade, a national bank, and several newspapers, and is the seat of Ashland University, a non-sectarian institution, founded in 1878. Pop. (1900) 4,087.

Ashland, Ore., city and county-seat of Jackson County; situated in the extreme southern part of the State, on the Southern Pacific Railroad, 341 miles south from Portland, and 431 miles northerly from San Francisco. Ashland is the seat of the Southern Oregon State Normal School, and has three public school buildings and eight church buildings. The city has an excellent municipal organization and police regulation. Ashland owns its own water system. There is an extensive electric-light and power plant, flour-mill, ice plant, sash and door factories, box factory, quartz-mill, foundry and machine shops, and three newspapers. The Southern Oregon Chautauqua Association is located here. There are valuable gold mines in the mountains near by, some of them almost within the city limits. In the vicinity are found great varieties of other valuable minerals, such as cinnabar, kaolin, marble, sandstone, etc. In the vicinity are many mineral springs, whose waters contain much in the way of medicinal properties. Pop. (1902) 4,000.

Ash'land, Pa., a borough in Schuylkill County, in the valley of the Mahanoy, and on several railroads; 12 miles northwest of Pottsville. It is in the centre of the great anthracite coal field, has extensive mining industries, large machine shops, foundries, and factories, and contains the State Miners' Hospital, a national bank, public hall, and several churches. Pop. (1900) 6,538.

Ash'land, Va., a town of Hanover County, situated on the Richmond, F. & P. R.R., 17 miles north of Richmond. It is the seat of Randolph-Macon College. It was the scene of several battles during the Civil War. Henry Clay's birthplace is within seven miles of the town. Pop. (1900) 1,147.

Ash'land, Wis., a city and county-seat of Ashland County, on Chequamegon Bay, Lake Superior, and several railroads; 80 miles east of Duluth. It has one of the finest harbors on the lake, and beside its general lake traffic is a shipping port for the hematite ore of the great Gogebic Iron Range. To accommodate its iron interests it has a number of enormous ore docks. Other important interests are lumber and brown stone. It has very large charcoal blast furnaces, used for the manufacture of pig iron, and since 1885, when the real development of the Gogebic iron mines began, the city has grown rapidly. Near by is the group of Apostles' Islands. The institutions include the North Wisconsin Academy, Sisters' Hospital (Roman Catholic), and Rhinehart Hospital. Pop. (1900) 13,074.

Ash'lar. See MASONRY AND BUILDING.

Ash'ley, Anthony Evelyn Melbourne, an English statesman: b. 1836. He is the fourth son of the seventh Earl of Shaftesbury, and in 1882 succeeded Mr. Courtney as under-secretary of state for the colonies.

Ash'ley, Lord. See SHAFTESBURY.

Ash'ley, William James, an Anglo-American economist: b. London, England, 25 Feb. 1860. He was graduated from Balliol College, Oxford, in 1881; was Fellow of Lincoln College, Oxford; lecturer in history in Lincoln and Cor-

pus Christi, 1885–8, and professor of political economy and constitutional history at the University of Toronto, Canada, 1888–92. He has been professor of economic history at Harvard University since 1892. He has written 'James and Philip van Artevelde' (1883); 'Introduction to English Economic History and Theory' (1888–93); 'Surveys, Historic and Economic' (1900); edited 'Economic Classics'; translated Schmoller's 'Mercantile System,' and has contributed a large number of articles to English and American economic journals.

Ash'mead-Bart'lett, Sir **Ellis,** an English politician: b. Brooklyn, N. Y., 1849; d. London, England, 19 Jan. 1902. He was educated at Christ Church College, Oxford, and admitted to the bar in 1877. He was examiner of the education department, 1874–80; Conservative member of Parliament from Suffolk, 1885, and from Sheffield, 1885-1902; civil lord of the admiralty, 1885, 1886; and was knighted in 1892. His popularity with political audiences in the early 80's was second only to that of Lord Randolph Churchill, but he lost much of this influence in later years owing to his association with the Turks and Swazis — a connection which subjected him to considerable ridicule in the House of Commons and the press. His chief literary production was 'The Battlefields of Thessaly' (1897), a record of his experiences in the last war between Greece and Turkey.

Ash'mole, Elias, a celebrated English antiquary: b. Lichfield, 1617; d. 1692. He practised as a chancery solicitor till the breaking out of the Civil War, when he retired to Oxford and entered himself of Brasenose College, and engaged in the study of natural philosophy, mathematics, and astronomy. At the Restoration he received the post of Windsor herald and other appointments, both honorable and lucrative. In 1672 appeared his 'History of the Order of the Garter.' Other works of his are: 'The Antiquities of Berkshire' (1719) and his 'Diary' (1717). He presented to the University of Oxford his collection of rarities, to which he afterward added his books and MSS., thereby commencing the Ashmolean Museum.

Ashmolean Museum, a museum at Oxford University, founded by Elias Ashmole (q.v.) in 1679. The building was erected by Sir Christopher Wren in 1682.

Ash'mun, George, an American lawyer: b. Blanford, Mass., 1804; d. 1870. He served for several years in the legislature of his native State and was prominent in Congress in 1845–50. He presided over the Chicago Convention which in 1860 nominated Lincoln for the presidency.

Ashmun, Jehudi, an American missionary: b. Champlain, N. Y., April 1794; d. Boston, Mass., 25 Aug. 1828. He prepared for the Congregational ministry, and became professor in Bangor Theological Seminary. Later he joined the Protestant Episcopal Church and edited one of its periodicals, 'The Theological Repertory.' He discovered his true vocation when he became an agent of the American Colonization Society and took charge of a reinforcement for the colony of Liberia in 1822. He found the colony utterly disorganized, but in six years his energy and ability had thoroughly reorganized it and he left it in a prosperous and orderly condition. He died soon after his return to the United States. He wrote 'Memoirs of Samuel Bacon' (1822), and his own life was written by R. R. Gurley (1839).

Ashochimi, ash-ō-chē-mē, or *Wappo.* A tribe of North American Indians who formerly ranged in California from the geysers to Calistoga hot springs and in Knight's Valley.

Ashraf, a-schräf', a town in Persia, near the southern coast of the Caspian Sea, 56 miles west of Astrabad. It was a favorite residence of Shah Abbas the Great, and was adorned by him with splendid buildings, of which only a few miserable ruins now remain.

Ashtabu'la, Ohio, city in Ashtabula County, on Lake Erie, at the mouth of the Ashtabula River; 54 miles east of Cleveland; on the New York, C. & St. L., the Pittsburg, Y. & A., and the Lake Shore & M. S. R.R.'s. It is the centre of an extensive agricultural and dairying region, and has large manufactories of leather, woolen goods, and farm implements. It has a Carnegie public library, three national banks, city hospital, and numerous large buildings. Its extensive railroad and lake commerce makes it an important transfer shipping point, especially for iron and coal. The city was first settled in 1801, was organized as a township in 1805, and incorporated as a city in 1892. On 29 Dec. 1876, a railroad accident here at a high bridge over the river resulted in the loss of over 100 lives. The city is governed by a mayor and city council elected biennially. Pop. (1890) 8,338; (1900) 12,949.

Ash'taroth, a goddess anciently worshipped by the Jews. Ashtaroth is the Astarté of the Greeks and Romans, and is identified by ancient writers with the goddess Venus (Aphrodite). She is probably the same as the Isis of the Egyptians. In Scripture she is almost always joined with Baal, and is called god, Scripture having no particular word for expressing goddess. She was the goddess of the moon; her temples generally accompanied those of the sun, and while bloody sacrifices or human victims were offered to Baal, bread, liquors, and perfumes were presented to Astarté.

Ashtavakra, ash-tä-va'krä. In Hindu legend, the hero of a story in the Mahabharata. His father, Kahoda, devoted to study, neglected his wife. Ashtavakra, though still unborn, rebuked him, and the angry father condemned the son to be crooked (hence the name, from *Ashtan,* eight, and *vakra,* crooked). At the court of Janaka, king of Mithila, Kahoda was defeated in argument by a Buddhist sage and was drowned in accordance with the conditions. In his 12th year Ashtavakra set out to avenge his father, and worsted the sage, who declared himself to be a son of Varuna sent to obtain Brahmins to officiate at a sacrifice. Kahoda was restored to life, and commanded his son to bathe in the Samanga River, whence the boy becomes perfectly straight. In the Vishnu Purana some celestial nymphs see Ashtavakra performing penance in the water and worship him. He promises them a boon and they ask the best of husbands. When he offers himself they laugh in derision at his crookedness. He cannot recall his blessing, but condemns them to fall into the hands of thieves.

Ash'ton, John, an English antiquarian: b. London, 22 Sept. 1834. He has published a long list of works on history, chap-books, legends, ballads, manners, and customs, caricature and satire, among which are 'Social Life in the Reign of Queen Anne' (1882); 'History of the Chap-books of the 18th Century' (1882); 'Social England under the Regency' (1890); 'When William IV. was King' (1896); 'Gambling in England' (1898); 'Florizel's Folly' (1899).

Ashton, Lucy, the heroine of Sir Walter Scott's novel, 'The Bride of Lammermoor.' Engaged to a man she loves, she is forced to marry another, and dies a maniac on her wedding day.

Ashton'-in-Mak'erfield, a town of Lancashire, England, 15 miles from Manchester, and noted for its potteries, collieries, and cotton-mills. Pop. (1901) 18,700.

Ash'ton-Un'der-Lyne, a market-town of Lancashire, England, 6 miles east of Manchester, on the north bank of the river Tame. It was an ancient Saxon town; the most interesting building is the parish church built in the reign of Henry V. Since 1769 it has grown rapidly through the extension of the cotton manufacture, both the spinning of cotton yarn and the weaving of calicoes being carried on in the town to a great extent. Upward of 20,000 work people are employed in factories. There are also collieries and iron-works in the neighborhood which employ a great many persons. Pop. (1901) 43,900.

Ashura'da, a small island in the southeast corner of the Caspian Sea. It is occupied by Russia as a naval and trading station.

Asia, the largest of the five continental divisions of the earth, lying eastward of the European and African continents, and separated from the American continent by Bering Strait and the Pacific Ocean. It is bounded north, east, and south, respectively, by the Arctic, Pacific, and Indian Oceans, with their various branches and inlets; it is divided from Africa on the southwest by the narrow isthmian Suez Canal; and is connected with Europe on the northwest across the whole breadth of that continent. The natural western boundaries are the Ural Mountains, the Caspian Sea, Caucasus Mountains, the Black Sea, Ægean Sea, the Mediterranean and Red Seas. The sinuosities of the Asiatic coast are very extensive; on the south the chief ocean inlets are the Gulf of Aden; the Arabian Sea with its inlets, the Gulf of Oman, the Persian Gulf, and the Gulfs of Cutch, Cambay, and Manar; and the Bay of Bengal containing the Gulf of Martaban. On the eastern or Pacific coast proceeding northward the principal indentations are the China Sea with the Gulfs of Siam and of Tonkin; the Tung-hai or Eastern Sea; the Hwang-hai or Yellow Sea with the Gulf of Pechili and Korea Bay; the Sea of Japan with the Gulf of Tartary; the Sea of Okhotsk; and Bering Sea with the Gulf of Anadyr. On the north or Arctic coast are the Nordenskjold Sea and the Kara Sea with the Gulf of Obi. The coast line is about 35,000 miles, giving a proportion of one mile of coast line to 496 square miles of surface. From the extreme southwestern point of Arabia, at the Strait of Bab-el-Mandeb to the extreme northeastern point of Cape Deshnef or East Cape, the length of Asia is about 6,900 miles, its breadth from Cape Chelyuskin or Northeast Cape in Siberia to Cape Romania, the southern extremity of the Malay Peninsula, is about 5,300 miles. The total area is estimated at 17,296,000 square miles. The most prominent features of the southern coast are the three great peninsulas of Arabia, India, and the Indo-Chinese Peninsula. The east coast is also flanked with insular and peninsular projections, forming a series of sheltered seas and bays. A series of large islands extends to the southeast of the continent, forming a connection with Australia; while a multitude of smaller islands are scattered over the Pacific and Indian Oceans. The principal peninsulas on the east are Kamchatka and Korea. The larger islands, proceeding from the northeast coast, are Saghalien, the Japanese Islands, the Philippine Islands, Borneo, Sumatra, Java, Celebes, the Moluccas, Papua or New Guinea, which, however, is Australasian rather than Asiatic, and lastly Ceylon at the southeastern extremity of the Indian Peninsula. The Kurile Islands, between Kamchatka and Japan, the islands of Loo Choo, Formosa, and Hainan on the Chinese coast, and the Andaman and Nicobar islands in the Indian Ocean, may also be noticed. On the west or Mediterranean coast the principal islands belonging to Asia are Cyprus and Rhodes. The northern coast, from East Cape or Deshnef, in Bering Strait, and on the Arctic Circle, to the Yalmal Peninsula, in the extreme northwest, is almost entirely contained within that circle. The highest point, Cape Chelyuskin, is about 78° N. The largest group of islands on the north coast is the Liakhov Islands (New Siberia); the largest indentation is the Gulf of Obi, which reaches below the Arctic Circle, and receives the river Obi about that latitude.

Mountains.— The mountain systems of Asia are of great extent, and their culminating points are the highest in the world. There are also vast plateaus and elevated valley regions, but large portions of the continent are low and flat. Such are the greater portions of Siberia, from the Ural Mountains across the north of the continent, and the western central region of the continent, where an area of great depression culminates in the Caspian. The greatest mountain system in Asia, and so far at least as altitude is concerned, of the world, is the Himalayan system, the principal mass of which lies between lon. 65° and 110° E. and lat. 28° and 37° N. It thus occupies a position not very far from the centre of the continent, though nearer the southern edge than the northern. It extends, roughly speaking, from northwest to southeast, its total length being about 2,000 miles, while its breadth varies from 100 to 500 or 600. Different names have been given to different portions of the system, such as Hindu Kush (the northwestern extremity), Karakoram, and Kuen-Lun, while Himalaya is more especially confined to the portion forming the northern barrier of Hindustan; but all these are really portions of the same connected mountain mass. The Kuen-Lun simply forms the northern flank of the mass, and is not, as it has been represented, a distinct chain; while the Karakoram Mountains have so little to distinguish them from the rest of the elevated mass

to which they belong that they may be crossed without the traveler being aware of it. The broadest part of the system, the elevated table-land of Tibet, lies between the Himalaya proper and the Kuen-Lun. The Tibetan Mountains are connected on the east with the mountains of China and with those that spread to the south-east over the Indo-Chinese Peninsula. The Thian-Shan is another great mountain system of Central Asia connected with the Himalayan system by the important Pamir Plateau or "roof of the world" in lon. 70°–80° east; lat. 37°–40° north. The point of junction forms "a huge boss or knot," from which the Thian-Shan runs northwestward for a distance of some 1,200 miles. Between these two systems, which curve round it on the west, lies eastern Turkestan, right in the centre of Asia. The greatest elevations of the Himalayan system are to be found among the Himalayas proper, where is Mount Everest, 29,002 feet high, Kunchinjinga, 28,156, etc. The principal passes here, which rise to the height of 18,000 to 20,000 feet, are the highest in the world. The Kuen-Lun summits reach a height of 22,000 feet. The Himalayas descend by successive slopes to the plain of northern India, which has an elevation of about 1,000 feet above the level of the sea. The Vindhyas cross the peninsula, dividing northern from southern India; the latter is further bounded by the eastern and the western Ghats, which run along the coasts; while the interior consists of elevated table-lands rising toward the south, where they attain in the neighborhood of the Nilgiri Hills an elevation of 7,000 feet. The Himalayas are not only connected with the mountains in the interior of India, and with ramifications into China and the Indo-Chinese peninsula, but on the west with the mountains of Baluchistan and Afghanistan. The Suliman and Hala ranges bound India on the west, and unite with the mountains of Baluchistan; while the Hindu Kush, passing westward through the north of Afghanistan, has continuations more or less distinct through Persia to the Elburz range south of the Caspian, and so onward to Mount Ararat. From this point again it forms connections with the mountains of Armenia, with the Caucasus, with the Taurus range in Asia Minor, and with the mountains which run to the south of Persia. The mountains belonging to this series form the boundaries of an elevated plateau extending from the Mediterranean to the Indus. On the north they are frequently of great elevation, Mount Demavend in the Elburz range reaching the height of 18,460 feet, while Ararat is nearly 17,000. The Thian-Shan system is continued to the northeast by the Altai and Sajansk ranges, the whole separating the Chinese Empire from Russian Turkestan and Siberia. Tengri-Khan in the Thian-Shan Mountains is estimated to have a height of 21,320 feet. A line of moderate elevation extends from the Altai westward to the Ural Mountains. To the east of the Sajansk range the Yablonoi Mountains run northeast toward the coast, along which they are continued northward under the name of Stanovoi to Bering Strait.

Table-lands, Plains, and Deserts.— Tibet forms the most elevated table-land in Asia, its mean height being estimated at 15,000 feet. Its surface is very rugged, being intersected by a number of mountain ranges running generally in an easterly and westerly direction. On the east it is bounded by lofty mountains which separate it from China. Some of the largest rivers of southern and southeastern Asia have their origin in Tibet, including the Indus, the Brahmaputra, the Yang-tse, and the Hoang-Ho. In this region, a numerous series of lakes run in a chain parallel to the Himalayas. Another great plateau, much lower, however, than that of Tibet, is the plateau of Iran, occupying a large portion of western Asia, extending from the Indus to the Mediterranean, and from the Persian Gulf to the Caspian Sea. It comprises the countries known as Afghanistan, Baluchistan, Persia, Armenia, and Asia Minor. It lies at altitudes varying from 2,000 to 8,000 feet above the sea. The eastern half of it consists to a large extent of unproductive wastes. Of great political and strategical importance at the junction of Turkestan, Afghanistan, and India, is the Pamir Plateau, already alluded to, called by the natives "the roof of the world." Its valleys are at an elevation of from 11,000 to 13,000 feet above the sea. Another table-land of smaller extent and elevation is the Deccan Plateau, India, south of the parallel of lat. 25° N. The principal plain of Asia, as already mentioned, is that of Siberia, which extends along the north of the continent and forms a vast alluvial tract sloping to the Arctic Ocean, and traversed by large rivers, such as the Obi, the Yenisei, and the Lena, that convey its drainage to that ocean. Vast swamps of peat-mosses called tundras cover large portions of this region. Southwest of Siberia, and stretching eastward from the Caspian to the Thian-Shan Mountains, is a low-lying tract, consisting to a great extent of steppes and deserts, and including in its area the Sea of Aral, Bokhara, Khiva, and other districts. This is a region of internal drainage, the rivers, among which are the Amu Daria and the Syr Daria, either falling into the Sea of Aral or into other smaller sheets of water. In the east of China there is an alluvial plain of some 200,000 square miles in extent, most of it productive and highly cultivated; in Hindustan there are plains extending for 2,000 miles along the south slope of the Himalayas; and between Arabia and Persia, watered by the Tigris and Euphrates, is the plain of Mesopotamia or Assyria, one of the richest in the world. Of the deserts of Asia the largest is that of Gobi, which is bounded on the north by the Yablonoi and Thian-Shan Mountains, on the south by Tibet, on the east by the Khingan Mountains on the borders of China; while in the west it extends into eastern Turkestan. Large portions of it are covered with nothing but sand or display a surface of bare rock. This desert forms a large part of the country known as Mongolia, the whole of which forms an area of internal drainage, deficient in rainfall. There are also extensive desert tracts in Persia, Arabia, and Hindustan. An almost continuous desert region may be traced from the African desert through Arabia, Persia, and Baluchistan to the Indus.

Rivers and Lakes.— Asia contains some of the largest rivers in the world. It is remarkable among the continents for the number of its rivers, some of them of large size, that never find their way to the ocean, their waters either

being lost in the sand or falling into lakes that have no outlet. The chief rivers in western Asia are the Tigris and Euphrates, that rise in the Armenian plateau and fall into the Persian Gulf; the Indus, from the Tibetan plateau, flows through northwestern Hindustan and falls into the Arabian Sea; the Ganges, which rises in the Himalayas and flows eastward through northern Hindustan, and the Brahmaputra, which rises in Tibet and flows through Assam and Bengal, both enter the Bay of Bengal; the Irrawaddy and the Salwen, rising in the mountains of the Indo-Chinese Peninsula, and both flowing through Burma, likewise enter the Bay of Bengal; the Mekong or Cambodia, the largest river of this peninsula, has its sources in the same mountains, and flowing southeastward enters the South China Sea; the Yang-tse and the Hoang-Ho, the two great rivers of China, rise in the Tibetan plateau; and enter the ocean after a winding easterly course; the Amur, the only other great river of eastern Asia, rises in Mongolia, and after a circuitous course enters the Sea of Okhotsk; the great rivers of northern Asia, the Lena, Yenisei, and Obi, have already been mentioned. The Yenisei is believed to have a length of 3,400 miles, the Yang-tse of at least 3,000, the Lena of 2,770, the Hoang-Ho of 2,600. The basin of the Obi, including of course those of its tributaries, the Tobol and the Irtish, is believed to be the largest of any river in the world, except the Amazon and the Mississippi, being considerably over 1,000,000 square miles in area.

The largest lake of Asia is the Caspian Sea, which, however, is partly in Europe, its largest tributary being the Volga. The chief Asiatic rivers falling into this sea are the Kur from the Caucasus, the Aras from Armenia, and the Atrek from northern Persia — the river Ural being partly European, partly Asiatic. The Caspian lies in the centre of a great depression, being 83 feet below the level of the Sea of Azof. East from the Caspian, as already mentioned, is the Sea of Aral, which, like the Caspian, has no outlet, and is fed by the rivers Amu Daria and Syr Daria. Its area is estimated at 27,000 square miles. Still farther east, to the north of the Thian-Shan Mountains, and fed by the Ili and other streams from this system, is Lake Balkash, a somewhat crescent-shaped sheet of water, with an area of 8,400 square miles. The lake has no outlet; its water is clear but very salt and disagreeable. There are also several other smaller lakes in this region, such as Issik-Kul, Kara-Kul, Ala-Kul, Baratala, etc. In the south of Siberia, between lon. 104° and 110° E., is Lake Baikal, a mountain lake from which the Yenisei draws a portion of its waters; its area is estimated at about 12,500 square miles. In the very centre of the continent is the Lob Lake, or Lob Nor, to which all the drainage of eastern Turkestan converges, being conveyed to it by the Yarkand, Kashgar, and other streams. These unite to form the Tarim River, which, from the source of the Yarkand, has a total length of over 1,200 miles. Lob seems to be rather a swampy tract than a lake proper. On the borders of Afghanistan, Persia, and Baluchistan, is a similar swampy lake that receives the Helmund and other streams from Afghanistan. Of the numerous lakes in Tibet Dangra-yum Nor and Tengri Nor seem to be the largest; the former is 45 miles long and 25 broad.

Geology.— Though in population and history the most ancient continent, geologically speaking Asia is considered, as regards its present aspect, to be one of the newest. The principal mountain chains are composed largely of granitic rocks. The Himalayan range of mountains bears a striking resemblance in geological structure to the Alps; they are composed of granite gneiss and mica-schist, with syenite and amphibolites or trap-rocks, particularly primitive greenstone; the Altai Mountains contain granite in layers without alternation of gneiss, argillaceous schist in contact with greenstone, and containing augite, jasper, calcareous rocks, argentiferous lead ore, and copper. The ramifications of the Altai into Russian Asia contain also coal-grit, schists, quartz, and greenstone, rich with lead, silver, and auriferous sand. The lower ranges are covered with transported layers of rolled stones of granite, gneiss, and porphyry, in which are found agates, carnelians, and chalcedonies. In the Kuen-Lun group are found rubies, lapis-lazuli, and turquoises. In the eastern part of the Urals the granite, of which the chain is composed, along with gneiss and other rocks, is extremely rich in iron and copper. The Caucasus contains granite, argillaceous schist, and basaltic porphyry. The great plains of northern India, Mesopotamia, central Asia, and Siberia are regarded as of very recent geological origin. From various indications many geologists are of opinion that the greater part of western Asia was occupied at no very distant period by an ocean, of which the Caspian and Aral Seas are the remains. It is also conjectured that a continental area extending across the Indian Ocean united Asia during the Permian period to Africa and Australia. Siberia is supposed to have been twice submerged during the Palæozoic and the later Tertiary period. A line of volcanic action extends on the eastern coast from Kamchatka through the Philippines and the Malay Archipelago to Aracan in the Bay of Bengal. In Kamchatka there are eight or nine active volcanoes; in the interior of the continent there appear to be none at present active.

Climate, Soil, etc.— The size of Asia, the great altitudes and depressions of the continent, along with the variations of latitude and the disposition of sea and land, etc., afford an inexhaustible source of complexity in the variety and distribution of climate. In Tibet, with a mean elevation of about 15,000 feet, the climate is rigorous, combining great cold with drought; vegetation is scanty, trees almost absent, and the population mostly nomadic; except in the lower valleys, where there is an agricultural population, it is very sparse. The climate of central Asia generally presents extremes of heat and cold, and great deficiency of rain. It has accordingly a deficient vegetation and a scanty nomadic population. The great region of Siberia, which, as already mentioned, is a level or slightly undulating plain, lying wholly within the temperate and frigid zones, has a climate which generally resembles that of similar latitudes in Europe, with the exception of greater heat and drought in summer and greater cold in winter. The rainfall is very moderate, but the drainage is deficient and the soil often becomes

swampy. The vegetation is scanty, consisting mostly of grasses and shrubs in the plains and pine forests on the mountains. There is very little land under cultivation and the population is very thin. The northern part of China to the east of central Asia has a temperate climate with a warm summer, and in the extreme north a severe winter. It is well watered and wooded, possesses a fertile and well-cultivated soil yielding the usual products of temperate regions, and is thickly peopled. The district lying to the south of the central region, comprising the two Indian peninsulas, southern China, and the adjacent islands, presents the characteristic climate and vegetation of the southern temperate and tropical regions. Here, however, the modifying effects of altitude come most largely into play, and every variety of climate and form of vegetation is to be found on the slopes of the Himalayas, and the mountains and plains of southern India and of the eastern peninsula. The part of Asia south of the Himalayas, though not all lying within the tropics, is all subject to tropical influences. Among the principal of these may be reckoned the effects of the tropical heat upon the air-currents. To this cause are due the trade-winds, which, carrying the moisture of the southern seas to the continents to be condensed by the mountain masses against which they strike, by determining the rainfall of the various continental districts, and affecting the size and course of the rivers, produce so many climatic effects. More local in their effects as well as arbitrary in their occurrence, and consequently fatal in their violence, are the cyclones, or circular storms, common in the Bay of Bengal and the China Sea. The normal directions of the monsoons are northeast and southwest; the northeast monsoon begins in April and the southwest in October; but the direction, duration, and intensity of these winds are greatly modified, especially on land, by local circumstances. The soil of the southern regions is usually good, and where moisture is sufficient vegetation is rich and even exuberant. The soil of India is so finely comminuted that it has been said it is possible to go from the Bay of Bengal to the Indus and return again to the sea without finding a single pebble. The rainfall in those regions is extremely irregular. There are belts where hardly any rain falls at all, others of moderate, and others of very heavy rainfall. On the Khasia Hills, to the northeast of the delta of the Ganges and Brahmaputra, the heaviest rainfall in the world takes place, the average fall observed being 550 inches a year. The principal period of rain is during the southwest monsoon. On the mountains which directly face the winds, charged with vapor as they come from the sea, the rain will fall in abundance, while they pass over intermediate plains without parting with their moisture. The rainfall, the course of the rivers, and the irrigation and fertility of the plains of India is accordingly determined by the position of the Himalayas, the Ghats, and other mountain ranges. The high plateau which extends from Asia Minor to the Indus has a temperate climate, with some extremity of heat in summer and cold in winter. Rain falls chiefly in winter and spring. The eastern part of this plateau is deficient in rain, and the soil is poor and unproductive, the western portion, consisting of Asia Minor, is more favored of nature. The desert character of large parts of Arabia, Persia, and Baluchistan has already been alluded to. Some parts of the coast of Arabia, as Yemen and Oman, are fertile, but the greater part, especially on the Red Sea, is barren and desolate. A desert belt surrounds an interior plateau of 1,000 to 3,000 feet in height, and of moderate fertility. Syria is divided between hilly and fertile and low desert tracts. The Japanese Islands, which are traversed by mountains of considerable elevation, and extend over about 15° of latitude, experience a great variety of climates. In the north the climate is rigorous, owing to the Siberian winds; in the south it is mild. The eastern coast is milder than the west, being sheltered by the mountain ranges from the cold winds of the continent. The country generally is fertile and populous. The character and productions of the other islands are mostly tropical.

A greater extreme of cold is reached in North America than in northern Asia, the mean temperature of the east coast of Siberia being above the zero of Fahrenheit; and the heat of southern Asia is less than that of Africa, which has more land lying within the tropics. In Siberia the extremes of temperature are great, exceeding 100° between the mean of the hottest and coldest month on the coast, and being commonly over 60° throughout the country. As the equator is approached the extremes of temperature diminish till at the southern extremity of the continent they approach within 5°. The highest temperature attained in southern Asia is about 112°, the highest mean about 82°. The summers of the northern latitudes, though shorter, attain a maximum of heat not much short of the tropics, the greater length of the day compensating for the less intensity of the midday heat. On the Persian plateau the summer heat is increased by the want of rain, and the severity of the winter by the elevation.

Vegetation.— The plants and animals of northern Asia generally resemble those of similar latitudes in Europe, though the extremes of climate are greater. The plateau extending from Asia Minor to the Himalayas resembles southern Europe in its productions, and the desert belt of Asia has an affinity to the African desert. The characteristic types of Siberia are continued to the high regions of central Asia. The community of type with European forms also extends to North China, where is developed besides a relation with the types of North America. The whole of northern Asia differs from Europe more in species than in genera of vegetable productions. Oaks and heaths are absent in Siberia. The principal mountain trees are the pine, larch, and birch; the willow, alder, and poplar are found in lower grounds. The cultivated plants of Asia Minor and Persia resemble those of southern Europe. In the central region European species reach as far as the western and central Himalayas, but are rare in the eastern. They are here met by Chinese and Japanese forms. The lower slopes of the Himalayas are clothed almost exclusively with tropical forms; higher up, between 4,000 and 10,000 feet, is the region of forests and cultivation, producing all the types of trees and plants that belong to the temperate zone, and having extensive forests of conifers; in the east forest trees are met with at a height of 13,000 feet.

Rhododendrons extend to 14,000 feet, and phanerogamous plants are found at the height of 19,500 feet. The southeastern region, including India, the Eastern Peninsula, and China, with the islands, contains a vast variety of indigenous species, varying with the humidity of the climate and the elevation, the forms of higher latitudes being represented on the mountains. In this region we find growing wild a number of plants that have become of the utmost importance to man, such as the sugar-cane, rice, cotton and indigo, pepper, cinnamon, cassia, clove, nutmeg, and cardamons, banana, cocoanut, areca and sago palms; the mango and many other fruits, with plants producing a vast number of drugs, caoutchouc and gutta-percha. The forests of India contain the oak, teak, sāl, deodar, and other timber woods, besides bamboos, palms, sandal-wood, laurels, fig-trees, etc. The Malay Peninsula contains dense forests of similar kinds. The cultivated plants of India include wheat, barley, rice, maize, millet, sorghum, tea, indigo, jute, opium, etc. North of the tropic wheat is sown in November, and reaped early in April, and a crop of rice or other tropical cereal is sown in June and July, and reaped in September and October. Wheat and barley do not grow in southern India, the winter not being sufficiently severe to prepare the ground for them. Cotton, indigo, sugar, tea, tobacco, coffee, pepper, plantains, mangoes, etc., are cultivated in China. Of the Chinese flora the larger portion resembles the Indian, while much is local. In North China, the country between it and the Amur (Manchuria), and the Japanese Islands, large numbers of deciduous trees occur, such as oaks, maples, limes, walnuts, poplars, and willows, the genera being European but the individual species Asiatic. Among cultivated plants are wheat, and in favorable situations rice, cotton, the vine, etc. Japan and the northern parts of this region are rich in species of the pine tribe. According to elevation the islands of the Asiatic Archipelago display an equal diversity with the mainland, the more tropical types being represented on the lower elevations, the more northern on the higher. Coffee, rice, maize, etc., are extensively grown in some of the islands. A line of demarkation called Wallace's line has been drawn at the Strait of Macassar, at which the flora and fauna of Australia begin to appear, and gradually become more pronounced as the distance from Asia and the proximity to Australia increases. The variety of plants of the desert region of Arabia, Persia, and Baluchistan is comparatively small. The predominance of a few species gives character to the whole region. Vegetation is most abundant in spring, when herbaceous and bulbous plants, which extend through this region from Syria to the Himalayas, are abundant. In Arabia Felix, and the warmer valleys of Persia, Afghanistan, and Baluchistan, where the hills are high enough to afford a sufficient rainfall, aromatic shrubs are abundant. Wheat, barley, cotton, and indigo are cultivated in Arabia, and the date-palm flourishes in the desert. On the mountain slopes of western Arabia (Arabia Felix) the coffee-plant, which has probably been derived from Africa, is cultivated. Gum-producing acacias are, with the date-palm, the commonest trees in Arabia; the latter also extends through Persia, and even reaches the shore of the Caspian. Fleshy plants are characteristic of the most arid portions. In the higher parts of Persia and Afghanistan numerous forms of *Umbelliferæ* of great size, as well as thistles and the borage tribe, are abundant. African forms are found not only extending from the African desert along the desert region of Asia, but from south Africa to Ceylon. The Caspian lowlands is the tract where the saline vegetation that is spread over the whole region of steppes and deserts has its greatest development. This region is regarded as the native country of the melon.

Zoology.— There is a still closer resemblance in the fauna than in the flora of northern Asia to that of Europe. Asia south to the Himalayas, together with Europe and North Africa, forms a continuous region, which Dr. Sclater has designated as the Palæarctic; southeastern Asia, with Sumatra, Java, Borneo, and the Philippines, he calls the Indian region; Africa south of the Atlas, with Arabia, Palestine, South Persia, the dry part of Baluchistan and Sind, form the Ethiopian region; Celebes and the other islands beyond Wallace's line, with Australasia, the Australian region. Nearly all the mammals of Europe occur in northern Asia, with numerous additions to the species. *Quadrumana* are rare, *Carnivora* numerous, especially bears, wolves, and weasels. Moles, shrews, and hedgehogs are common among *Insectivora.* Rodents are represented by marmots, the pika, jerboas, rats, mice, etc. There are numerous species of wild sheep, antelopes, and deer. Of the last, the musk and many others are characteristic. In the Indian region there are several peculiar genera of the *Quadrumana* or monkey tribe. Among the distinctive forms of this region is the elephant, the Asiatic species being distinct from the African. The lion, tiger, leopard, which are considered as Ethiopian forms, the bear, civets, ichneumons, and other carnivorous animals are found. The lion inhabits Arabia, Persia, Asia Minor, Baluchistan, etc., and extends as far east as India, being now, however, confined to Guzerat. The tiger is the most characteristic of the larger Asiatic *Carnivora.* It extends from Armenia across the entire continent, being absent, however, from the greater portion of Siberia and from the tableland of Tibet; it extends also into Sumatra, Java, and Bali. The horse, ass, and camel have their true home in Asia. In the Indian region we also find the rhinoceros, buffalo, ox, deer, squirrels, porcupines, as well as various species of *Edentata.* The ornithology of Europe and northern Asia are identified to a still greater extent. A large number of European species extend over northern Asia as far as Japan. In the Malay Archipelago marsupial animals first occur in the Moluccas and Celebes, while various mammals common in the western part of the archipelago are absent. A similar transition toward the Australian type takes place in the species of birds. Of marine mammals the dugong is peculiar to the Indian Ocean; in the Ganges is found a peculiar species of dolphin. In birds, nearly every order except ostriches is represented. Among the most interesting forms are the hornbills, the peacock, the Impey pheasant, the tragopans, and other gallinaceous birds, the pheasant family being very characteristic of the region. The pheasant proper in the wild state is peculiar

.o northern Asia, the golden pheasant and several other species of pheasants to the northeast. The genera and species of passerine birds are very numerous. The desert region, extending from Arabia to Sind, is chiefly distinguished by the absence of many Indian forms and the presence of some African ones, which, however, are not widely spread, most of them being limited to Arabia and Syria. The chief haunts of the *Reptilia* of Asia are the northern portion of Hindustan, the southeastern peninsula, China, and the islands of Ceylon, Sumatra, and Java. At the head of the reptiles stands the Gangetic crocodile, frequenting the Ganges and other large rivers; the helmeted crocodile and the double-crested crocodile are numerous in various quarters, both insular and continental. Among the serpents are the cobra da capello and the Ceylonese tic-palonga, both among the most deadly snakes in existence; there are also very large pythons, besides sea and fresh-water snakes. There are also a number of species of frogs and toads and of fresh-water tortoises, as well as many terrestrial and aquatic lizards. The seas and rivers of Asia produce a great variety of fish. The *Salmonidæ* are found in rivers flowing into the Arctic and North Pacific oceans, but not in southern Asia. Large numbers are caught. Trout are found in the feeders of the Indus and the Caspian. Sturgeons abound in the Black Sea and the Caspian. Two rather remarkable kinds of fishes are the climbing perch and the eriapthalmus. The well-known gold-fish is a native of China.

Asiatic Races.— The Mongolian race is the most numerous in Asia. It occupies the Chinese empire, Tartary, and probably Japan, with part of the Indo-Chinese Peninsula. It is partly settled, as in China, Japan, and the peninsula; partly nomadic, as in Tartary and Mongolia. The Aryan is the next in numbers, and the most civilized of the Asiatic races. It was until the Mohammed conquest the dominant, as it is still the most numerous, race in India. It also prevails in Persia and in the middle region from Afghanistan to Asia Minor. The Semitic race is widely spread in southwestern Asia, and formerly at least extended to Africa. The Dravidian race in South India, the Malays in the eastern peninsula, and other races locally distributed, have no well-defined relation with the larger races. The Dravidians are variously associated with the Mongols and the Australians. The latter theory is connected with the hypothesis of a southern continent, which also connects these races with Africa. See ETHNOLOGY.

Political Divisions.— A large portion of Asia is under the dominion of European powers. Russia possesses the whole of northern Asia (Siberia) and a considerable portion of central Asia, together with a great part of ancient Armenia, on the south of the Caucasus; Turkey holds Asia Minor, Syria, and Palestine, part of Arabia, Mesopotamia, etc.; Great Britain rules over India, Ceylon, a part of the Indo-Chinese Peninsula (Upper and Lower Burma), and one or two other possessions; France has acquired a considerable portion of the Indo-Chinese Peninsula (Cochin-China, Anam, Tonkin, Cambodia), and has one or two small settlements besides, while to Holland belong Java, Sumatra, and other islands or parts of islands in the Asiatic or Malay Archipelago. The chief independent states are the Chinese empire, much the most populous of all; Japan, Korea, Siam, Afghanistan, Persia, and the Arabian states. The total population of the continent is estimated at 905,000,000.

Religions.— Asia has been the birthplace of religions; the Jewish, Buddhist, Christian, and Mohammedan having their origin in Asia, where they grew up under the influence of still older religions, the Babylonian and that of Zoroaster, both also of Asiatic origin. At present the inhabitants of Asia belong chiefly to the Buddhist religion, which has 530,000,000 to 560,000,000 of followers, that is, nearly one third of mankind. The old faith of Hinduism has 187,000,000 of followers in India. Most of the inhabitants of western Asia, as also of part of central Asia, follow the religion of Islam; they may number about 90,000,000. The Christians number about 20,000,000 in Armenia, Caucasus, Siberia, and Turkestan. Jews are scattered mostly in western and central Asia. A few fire-worshippers, Guebers or Parsi of India and Persia, are the sole remnant of the religion of Zoroaster; while vestiges of Sabæism are found amidst the Gesides and Sabians on the Tigris.

Civilization.— There are to be found in Asia all varieties of civilization, the primitive tribes of northeastern Siberia, the confederations of nomadic shepherds, and great nations in possession of a common stock of national customs, beliefs, and literature, like China; the tribal stage; the compound family, forming the real basis of China's social organization; the rural community, both of the Indian and Mussulman type; the loose aggregations of Tchuktchis, having no rulers and no religion beyond the worship of forces of nature, but professing with regard to one another principles of morality and mutual support often forgotten in higher stages of civilization; and despotic monarchies with a powerful clergy. So also in economic life. While the tribes of the northeast find their means of subsistence exclusively in fishing and hunting, carried on with the simplest implements, among which stone weapons have not yet quite disappeared, and the tribes of central Asia carry on primitive cattle-breeding and lead a half-nomadic life, others are agriculturists, and have brought irrigation (in Turkestan) to a degree of perfection hardly known in Europe.

Internal Communication.— Caravans of camels are the chief means of transport for goods and travelers in the interior; donkeys, yaks, and even goats and sheep are employed in crossing the high passages of the Himalayas; horses are the usual means of transport in most parts of China and Siberia, and in the barren tracts of the north the reindeer and, still farther north, the dog, are made use of. Fortunately the great rivers of Asia provide water communication over immense distances. The deep and broad streams of China, allowing heavy boats to penetrate far into the interior of the country, connect it with the sea; a brisk traffic is carried on along these arteries. In Siberia the bifurcated rivers supply a waterway, not only north and south along the course of the chief rivers running toward the Arctic Ocean, but also west and east; thus a great line of water communication crosses Siberia, and is, with but a few interruptions, continued in the east by the Amur, navigable for more

than 2,000 miles. In the winter the rivers and plains of Siberia become excellent roads for sledges, on which goods are still chiefly transported.

Railways.— In 1900 the lines in existence had a total length of about 30,000 miles, of which two thirds belonged to British India. The portions of the trans-Caspian and trans-Siberian railways already constructed had a length of 3,200 miles. A number of European syndicates held concessions for 3,600 miles of railroads in China, which will traverse regions rich in minerals and agriculture; many of these lines were then in process of construction. The Chinese government owned about 300 miles of railway. The lines are very remunerative, especially that from Peking to Tien-Tsin. Japan is well provided with railroads; the length being 3,200 miles. French Indo-China had only 120 miles, but the French possessions in Cochin-China, Anam, and Tonkin are expected soon to have 2,400 miles, which will greatly help to develop their mineral and agricultural resources. The Dutch Indies are well supplied. Java alone has 1,000 miles. There are as yet no railroads in Persia of any consequence; but Turkey operates 1,500 miles in Asia, and 600 miles more are in construction or projected.

Telegraph communications are in a much more advanced state than the roads. St. Petersburg is connected by telegraph with the mouth of the Amur and Vladivostock (on the frontier of Korea); while another branch, crossing Turkestan and Mongolia, runs on to Tashkend, Peking, and Shanghai; Constantinople is connected with Bombay, Madras, Singapore, Saigon, Hong-Kong, and Nagasaki in Japan; and Singapore stands in telegraphic communication with Java, and Port Darwin in Australia. Finally, Odessa is connected by wire with Tiflis in Caucasus, Teheran, and Bombay.

Trade.— Notwithstanding the difficulties of communication a brisk trade is carried on between the different parts of Asia, but there is no possibility of arriving at even an approximate estimate of its aggregate value. The maritime exports to Europe, the United States, and overland to Russia, have an annual value of about $900,000,000, and the imports of about $750,000,000. Asia deals chiefly in raw materials, gold, silver, petroleum, teak, and a variety of timber-wood, furs, raw cotton, silk, wool, tallow and so on; the products of her tea, coffee, and spice plantations; and a yearly increasing amount of wheat and other grain. Steam industry is only now making its appearance in Asia, and, although but a very few years old, threatens to become a rival to European manufacture. Indian cottons of European patterns and jute-stuffs already compete with the looms of her European sister countries. Several of the petty trades carried on in India, China, Japan, Asia Minor, and some parts of Persia, have been brought to so high a perfection that the silks, printed cottons, carpets, jewelry, and cutlery of particular districts far surpass in their artistic taste many like productions of Europe. The export of these articles is steadily increasing, and Japan supplies Europe with thousands of small articles — applications of Japanese art and taste to objects of European household furniture.

History.— The origin of the name Asia is involved in obscurity, and it is not certainly known whether it arose among the Greeks or was borrowed by them from some Asiatic people. The Greeks seem to have applied it originally only to Lydia, the part of the continent with which they first became acquainted. Modern scholars are inclined to believe that the name Asia is connected with the Sanskrit *ushas,* the dawn, as Europe may be connected with the Hebrew *ereb,* the west or the sun-setting.

The oldest historical documents are of Asiatic origin, and next to the immediately contiguous kingdom of Egypt Asia possesses the oldest historical monuments in the world.

The oldest historical monuments in Asia are those of Assyria (see ASSYRIA), and with them are associated traditions which carry us back to a remote and indefinite antiquity. A similar vague antiquity belongs to the historical traditions of India and China. Criticism, however, reduces all these claims to moderate dimensions, and assigns to the oldest ascertained facts a period not more remote than some 4,000 years from the present.

The earliest facts in the history of Asia, apart from documents and monuments, consist in the migrations of races, the evidence of which is derived from tradition, from language, from customs, and from religion. The earliest known seat of the Aryan race was on the banks of the Oxus. Hence probably from the pressure of the Mongolian tribes to the north they spread themselves to the southeast and southwest, pressing upon the Dravidian inhabitants of India and the Semitic races of southwestern Asia. Finally they drove the Dravidians to the south of India and occupied Persia and other parts of western Asia, spreading into Europe. It is a remarkable circumstance that in this invasion the Aryans appear to have acquired the use of letters from the peoples with whom they came in contact, the Dravidian letters being borrowed in India and the Semitic in Persia as the original basis of the Sanskrit and Zendic alphabets. At a later period the Greeks likewise adopted a Semitic alphabet from the Phœnicians. The Semites have spread within historical times into northern Africa, and their migrations had probably taken a similar course before they were recorded in history. A large portion of the Mongols are still, as they have always been, a nomadic race, and their migrations, carrying everywhere the terror of predatory arms, have spread from the settled part of their own race in China along the north of Asia into northern Europe.

The early religion of the Aryan race,— a nation of shepherds,— divided itself after their separation into two related but widely different developments, Brahmanism and Zoroastrianism. (See INDIA (*Religion*); ZEND-AVESTA.) The former became rich in mythological, theological, and philosophical literature; but historical literature properly so called is wanting, and consequently there is a great absence of certainty with regard to the dates of early events. The war which the Mahâbhârata (see SANSKRIT LANGUAGE AND LITERATURE) professes to narrate is believed to be the earliest event in Indian history that can be regarded as historical, and probably took place about 1200–1400 B.C. In China authentic history extends back prob-

ably to about 1100 B.C., with a long preceding period of which the names of dynasties are preserved without chronological arrangement. The kingdoms of Assyria, Babylonia, Media, and Persia, alternately predominated in southwestern Asia. The arms of the Pharaohs also extended into Asia, but their conquests there were short-lived. From Cyrus (B.C. 559), who extended the empire of Persia from the Indus to the Mediterranean, while his son, Cambyses, added Egypt and Libya to it, to the conquest of Alexander (B.C. 330), Persia was the dominant power in Asia. The administration of Persia was not without vigor and policy, yet the Macedonian conquest was an event of great importance to Asia, bringing it, along with northern Africa, into closer relation with the more advanced and progressive continent of Europe. The division of Alexander's empire led to the protracted struggle between the Greek dynasties of Egypt and Syria, which ended in the absorption of both kingdoms in the Roman empire. After the unfortunate issue of the second Punic war Hannibal took refuge with Antiochus the Great of Syria, who, in the course of his conquests, had come in contact with the Romans, and was at length incited to try his strength with them. In the course of the war with Antiochus L. Scipio, together with his brother, the conqueror of Carthage, passed into Asia. The kingdom of Antiochus was spared after his overthrow; but in B.C. 65 Syria became a Roman province. The Roman empire ultimately extended to the Tigris.

The knowledge of Asia possessed by the Greeks and Romans was at its widest extent very limited. The countries with which they were best acquainted were naturally in the west. China they knew as the country of the Seres or Sinæ, and the northern portions of the continent, inhabited by predatory Mongol tribes, were vaguely designated as Scythia. Of India the northwestern and western parts were known, and Ceylon likewise, under the name of Taprobane. The country traversed by the Hindu Kush, and the sources of the Oxus, was known as Bactria; that between the Oxus and the Jaxartes as Sogdiana; a large and vaguely defined central district, including Persia, was known as Ariana. Ptolemy had some acquaintance with the Indian Peninsula, with the table-land of cental Asia, with the Himalayas (Imaus) and China. The better known countries of the southwest comprised Asia Minor, Armenia, Arabia, Persia, Media, Parthia, Mesopotamia, Babylonia, Assyria, Syria.

Soon after the most civilized portions of the three continents had been reduced under one empire the great event took place which forms the dividing line of history. Christianity spread rapidly in the Roman empire; but Armenia was the first country which received it as a national religion. In A.D. 226 the Parthian monarchy which had arisen in eastern Persia about B.C. 250, and had disputed the empire of Asia with the Romans, was overthrown by the revived Persian dynasty of the Sassanidæ. The empire of Asia was now disputed with the Romans by the Persians. In the revived Persian empire the Magian religion was restored, and after the establishment of Christianity in the Roman empire religious jealousy embittered the feud between the two powers. The possession of Armenia was the subject of a protracted struggle between them; but its religion inclined it to the Roman alliance. The Tigris formed the most permanent boundary between the two empires, neither being able long to maintain any conquests beyond it. Christianity was persecuted in the Persian empire, and could not extend itself freely beyond the Roman limits. After the division of the Roman empire (A.D. 364) the struggle continued between the eastern and the Persian empires until the rise of a new power destined to absorb them both. While the Eastern empire was struggling more and more feebly with the Persians, the Mongols, and the barbarians of Europe, a new religion arose in Arabia (A.D. 622), which gathered around it a band of enthusiasts, small at first, but inspired with the most ardent zeal of proselytism. The central tenet of the unity of God gave them the sympathy of the Monophysite sect, which, persecuted in the empire, was powerful in Egypt, Syria, Mesopotamia, and Armenia. Arabia, the country of the Prophet, soon gave its adherence to the new faith. The sword was consecrated as the instrument of its propagation. Persia was the first great conquest of the Arabians. Syria and Egypt soon fell before their arms, powerfully aided by the defection of the heretics of the empire, and within 40 years of the celebrated flight of Mohammed from Mecca, which constitutes the era of his followers, the sixth of the Caliphs, or successors of the Prophet, was the most powerful sovereign of Asia. Heraclius, one of the most warlike, and in the early part of his reign one of the most successful of the eastern emperors, had succumbed to this torrent of conquest, and his successors trembled at the names of their rivals. The successors of Mohammed were at first austere and simple in their manners, and narrow and zealous in their religious faith; but from the accession of Moawiyah (A.D. 661), the time when the seat of empire was transferred first to Damascus and subsequently to Bagdad, the throne of the Caliphs was as splendid as it was powerful. The generous blood of Arabia, nourished by more genial climes, showed an aptitude for all that is great, not only in military achievement, but in learning, science, literature, and art. The empire was soon divided, but wherever the Arab sway prevailed a liberal patronage of learning and toleration even of speculative inquiry distinguished it. The career of conquest was not soon ended. It spread with astonishing rapidity over Africa and Europe, and was finally checked only by the fatal divisions which originated in the disputes between the descendants of the Prophet and the dynasty of the Ommiades, descended from his mortal foe and tardy convert, Abu Sophian.

Among the alternate protectors and oppressors of the eastern Roman empire were the various Mongol tribes, whose predatory course led them to the west. In these also the Arab rulers found dangerous converts, who first supplied the place of their own troops, grown effeminate with luxury, and then supplanted themselves in the throne of which they had superseded the natural defenders. While the Caliphs of Bagdad still held a nominal sway, subject to the dictation of their Turkish guards, Mahmud, the Mongolian Mohammedan ruler of Ghazni, asserted his independence (999), con-

quered India, and established the Mogul dynasty. Another revolt from the empire of Mahmud founded the Seljuk dynasty, which established itself in Aleppo, Damascus, Iconium, and Kharism, and which was distinguished for its struggles with the Crusaders. Othman, an amir of the Seljuk sultan of Iconium, established the Ottoman empire in 1300. About 1220 Genghis Khan, an independent Mongol chief, made himself master of central Asia, conquered northern China, overran Turkestan, Afghanistan, and Persia; his successors took Bagdad and extinguished the remains of the Caliphate. In Asia Minor they overthrew the Seljuk dynasty. His grandson, Kublai Khan, conquered China in 1260. The successors of Genghis Khan also invaded Russia, and the Christian empire established by Vladimir was overthrown by the Golden Horde, led by his grandson Batu (1240). Timur or Tamerlane, who professed to be a descendant of Genghis, carried fire and sword over northern India and western Asia, defeated and took prisoner Bajazet, the descendant of Othman (1402), and received tribute from the Greek emperor. The Ottoman empire soon recovered from this blow, and Constantinople was taken and the Eastern empire overthrown by the Sultan Mohammed II. in 1453. China recovered its independence about 1368 and was again subjected by the Manchu Tartars (1618–45), soon after which it began to extend its empire over central Asia. Siberia was conquered by the Cossacks on behalf of Russia (1580–4). The same country effected a settlement in the Caucasus about 1786, and has since continued to make steady advances into central Asia. The discovery by the Portuguese of the passage to India by the Cape of Good Hope led to their establishment on the coast of the peninsula (1498). They were speedily followed by the Spanish, Dutch, French, and British. The struggle between the two last powers for the supremacy of India was completed by the destruction of the French settlements (1760–65), and from that time the conquest of India by the British progressed with uninterrupted success. In 1858 India came directly under the British crown. The extension of the influence and possessions of European powers, especially Russia, Great Britain, and France, has latterly been a most striking fact in Asiatic history. For particular phases of the modern history of Asia see CHINA; KOREA; JAPAN; MANCHURIA; RUSSIA and TURKEY. Also BOXERS and TRIPLE ALLIANCE.

A'sia, Central, a designation loosely applied to Asiatic territory east of the Caspian, also called Turkestan, and formerly Tartary. The eastern portion belongs to China, the western now to Russia. Russian central Asia comprises the Kirghiz Steppe (Uralsk, Turgai, Akmolinsk, Semipalatinsk, etc.), and what is now the government-general of Turkestan, besides the territory of the Turkomans, or Tanscaspia and Merv. The entire area is about 1,350,000 square miles. See Bouvalot, 'Through the Heart of Asia' (1889); Phibbs, 'Central Asia' (1899).

Asia Minor (Asia the Less) is the extreme western peninsular projection of Asia, forming part of Turkey in Asia. The name is not very ancient; originally the Greeks seem by Asia to have meant only the western part of Asia Minor, but with their geographical knowledge the scope of the name Asia gradually widened. The late Greek name for Asia Minor is Anatolia — *Anatolê,* "the East," whence is formed the Turkish *Anadōli.* Asia Minor includes the peninsula; the eastern boundary, somewhat artificial, being a line from the Gulf of Skanderoon to the upper Euphrates, and thence to a point east of Trebizond. The area of the peninsula exceeds 220,000 square miles. It constitutes the western prolongation of the high table-land of Armenia, with its border mountain ranges. The interior consists of a great plateau, or rather series of plateaus, rising in graduation from 3,500 to 4,000 feet, with bare steppes, salt plains, marshes, and lakes; the structure is volcanic, and there are several conical mountains, one of which, the Ergish-dagh (Argæus), with two craters, attains a height of 11,830 feet, towering above the plain of Kaisarieh, which has itself an elevation of between 2,000 and 3,000 feet. The plateau is bordered on the north by a long train of parallel mountains, 4,000 to 6,000 feet high, and cut up into groups by cross valleys. These mountains sink abruptly down on the northern side to a narrow strip of coast; their slopes toward the interior are gentler and bare of wood. Similar is the character of the border ranges on the south, the ancient Taurus, only that they are more continuous and higher, being, to the north of the Bay of Skanderoon, 10,000 to 12,000 feet, and farther to the west, 8,000 to 9,000 feet. The western border is intersected by numerous valveys opening upon the archipelago, to the northern part of which Mounts Ida and Olympus belong. Between the highlands and the sea lie the fertile coast-lands of the Levant. Of the rivers the largest is the Kizil Irmak (Halys), which, like the Yeshil Irmak (Iris), and the Sakaria (Sangarius) flows into the Black Sea; the Sarabat (Hermus) and Meinder (Mæander) flow into the Ægean.

The climate has, on the whole, a southern European character; but a distinction must be made of four regions. The central plateau, nearly destitute of wood and water, has a hot climate in summer, and a cold one in winter; the southern coast has mild winters and scorching summers; while on the coast of the Ægean there is the mildest of climates and a magnificent vegetation. On the northern side the climate is not so mild, but the vegetation is most luxuriant.

In point of natural history, Asia Minor forms the transition from the continental character of the East to the maritime character of the West. The forest-trees and cultivated plants of Europe are seen mingled with the forms characteristic of Persia and Syria. The central plateau, which is barren, has the character of an Asiatic steppe, more adapted for the flocks and herds of nomadic tribes than for agriculture; while the coasts, rich in all European products, fine fruits, olives, wine, and silk, have quite the character of the south of Europe, which on the warmer and drier southern coast shades into that of Africa.

The inhabitants, some 7,000,000 in number, consist of the most various races. The dominant race are the Osmanli Turks, who number about 1,200,000, and are spread over the whole

country; allied to these are the Turkomans and Yuruks, speaking a dialect of the same language. The latter are found chiefly on the table-land, leading a nomadic life; there are also hordes of nomadic Kurds. Among the mountains east of Trebizond are the robber tribes of the Lazes.

The Greeks and Armenians are the most progressive elements in the population, and have most of the trade. While the Greeks monopolize the professions, the ownership of the land is largely passing into the hands of Greeks, Armenians, and Jews. Administratively the country falls into eight vilayets or governments, with their capitals in Brusa, Smyrna, Konieh (Iconium), Adana, Sivas, Angora, Trebizond, and Kastamuni respectively. In ancient times the divisions were Pontus, Paphlagonia, Bithynia, in the north; Mysia, Lydia, Caria, in the west; Pisidia with Pamphylia, and Cappadocia, in the south; and Galatia with Lycaonia and Phrygia, in the centre. The Turkish islands of the archipelago belong, most of them, to Asia Minor.

Here, especially in Ionia, was the early seat of Grecian civilization, and here were the countries of Phrygia, Lycia, Caria, Paphlagonia, Bithynia, Lydia, Pamphylia, Isauria, Cilicia, Galatia, Cappadocia, etc., with Troy, Ephesus, Smyrna, and many other great and famous cities. Here, from the obscure era of Semiramis (about 2000 B.C.) to the time of Osman (about 1300 A.D.), the greatest conquerors of the world contended for supremacy; and here took place the wars of the Medes and Persians with the Scythians; of the Greeks with the Persians; of the Romans with Mithridates and the Parthians; of the Arabs, Seljuks, Mongols, and Osmanli Turks with the weak Byzantine empire. Here Alexander the Great and the Romans successfully contended for the mastery of the civilized world. But notwithstanding all these wars the country still continued to enjoy some measure of prosperity till it fell into the hands of the Turks, under whose military despotism its ancient civilization has been sadly brought to ruin. Recently, considerable portions of Armenia have been absorbed by Russia. In 1878 Great Britain made a secret engagement to guarantee against Russian aggression the Asiatic dominions of the Porte.

In Asia Minor an extensive system of railroads has long been under consideration. The first survey for this proposed trunk line was made as far back as 1874, and was from Angora to Bagdad. The financial crisis of 1875 resulted, however, in the abandonment of the scheme, but it was again considered in 1888 by foreigners interested in railroad enterprise in Asia. The Suitari-to-Angora line was conceded in October of that year to the Bank of Berlin, and on 27 Nov. 1892 the first train was run. A branch line was shortly after built between Eski-Schehir and Konia and connected with the line to Smyrna. The success of this undertaking influenced the Sultan's desire to have the line extended to Bagdad across Mesopotamia, and the German syndicate was instructed accordingly. The survey was made in the winter of 1899–1900 by a commission under the presidency of the German consul-general at Constantinople. Matters were hastened by the request of the Emperor William that the work be pushed forward as rapidly as possible.

Asiarch, ä'shī-ärk, a Roman officer appointed as director-general of religious ceremonies in the province of Asia. The expression occurs in the Greek Testament, *Tines de kai tōn Asiarchōn,* "And certain also of the Asiarchs" (Acts xix. 31). Properly speaking there was but one Asiarch residing at Ephesus; the others referred to were his subordinates.

A'siat'ic Broth'ers, the designation of a secret society organized in Germany about 1780. See ROSICRUCIANS.

A'siat'ic Societies, learned associations formed for the purpose of collecting and disseminating valuable information respecting the different countries of Asia. The Royal Asiatic Society of Great Britain and Ireland was established 19 March 1823. With it in 1828 was connected a very active translation committee, which publishes English, French, and Latin translations of Oriental works, occasionally accompanied with the originals. Similar societies have been formed in Asia itself, such as the Asiatic Society of Bengal at Calcutta, founded in 1784 by Sir William Jones. Since 1846 the Bibliotheca Indica,— a series of Oriental works in text and translation,— has been published under the supervision of this society at the expense of the Anglo-Indian government. There are similar societies on the Continent and in America, such as the Société Asiatique at Paris, founded in 1822, the Oriental Society of Germany (Deutsche Morgenländische Gesellschaft), founded in 1845, and the American Oriental Society.

Asimina, a-sĭm'ĭ-na, or ăs'ĭm-ĭ-nă, **Papaw,** a genus of nine species of shrubs or small trees of the natural order *Anonaceæ,* eight of which are natives of eastern North America, the West Indies, and Mexico, with attractive foliage and large purple or whitish axillary flowers appearing in early spring, and large edible berries. Two species are cultivated for ornament and deserve more attention at the hands of horticulturists. One of these, *A. triloba,* which has produced some varieties, is the only arborescent species of the genus. It is hardy as far north as Massachusetts and produces very large seeded fruits, often more than three inches long and too highly aromatic to suit all palates. The other species, *A. grandiflora,* is found in Georgia and Florida, and is said to produce delicious fruits.

A'siphona'ta, an order of lamellibranchiate, bivalve mollusks, destitute of the siphon or tube through which, in the Siphonata, the water that enters the gills is passed outward. It includes the oysters, the scallop shells, the pearl oyster, the mussels, and in general the most useful and valuable mollusks.

Ask, in Scandinavian mythology, the name of the first man created. According to the legend, the gods, Odim, Hæner, and Loder, found two trees by the seaside, an ash and an elm. From these they created the first man and first woman, Ask and Embla, and gave them the earth as their dwelling place.

Askew, ăs'kū, **Anne,** an English martyr: b. 1521; d. 16 July 1546. She is described as a lady of great beauty and learning, married, much against her inclinations, to Thomas Kyme, who was as attached to the old religion as she was to the new. She was arrested for heresy

and led before Bonner, Bishop of London, who induced her to sign a recantation. She was again arrested, however, committed to Newgate, and condemned to death as a heretic. Some days later she was suddenly removed to the Tower, and the rack was applied in the presence, and it is said even by the hands, of Wriothesley, the chancellor, who hoped to extort confession concerning those ladies of the court with whom she corresponded. Before her frame had time to recover from the effects of the rack she was carried in a chair to Smithfield, chained to a stake, and along with four others was burned to death.

Askhabad, äs'ka-bäd', the thriving administrative centre of the Russian province of Transcaspia, situated in the Akhal Tekke oasis, and occupied by Skobeleff in January 1881, after the sack of Geok Tepé. Its distance from Merv is 232 miles, from Herat 388 miles. Pop. (1897) about 20,000.

Askja, äsk'ya, a volcano in the centre of Iceland, first brought into notice by an eruption in 1875. Its crater is 17 miles in circumference, surrounded by a mountain-ring from 500 to 1,000 feet high, the height of the mountain itself being between 4,000 and 5,000 feet.

Aslauga's (a-slow'găz) **Knight,** the title of a romantic tale of mediæval chivalry, by Fredrich, Baron de la Motte, Fouqué. It was published in 1814. The story is told with simplicity and grace, and with it may be compared 'The Fostering of Aslang' in Wm. Morris' 'Earthly Paradise.'

Asmai, äs'mī, or **Asmayi,** an Arabic writer, the instructor of Harun-al-Raschid: b. about 740; d. 830. His history of the kings of Arabia and Persia, prior to Islam, is of great value, while his romance of 'Antar' has been called "the iliad of the desert."

As'manite, a variety of silica, occurring in small grains in certain meteoric irons, and now believed to be identical with tridymite (q.v.).

Asmannshausen, äs'mans-how'zĕn, a Prussian village on the Rhine, in the district of Wiesbaden, below Rüdesheim, celebrated for its wine, which is produced on a soil formed of blue slate. The red kind, the production of a small red Burgundy vine, is the more valuable, but retains its value only three or four years. After this time it grows worse every year, and precipitates the whole of its red coloring-matter. It is distinguished by color and taste from all other Rhenish wines.

As'mode'us, or **Asmo'dai,** in Hebrew mythology, an evil spirit which slew seven husbands of Sara, daughter of Raguel, at Rages. By the direction of the angel Raphael the young Tobias exorcised Asmodeus with the smell of a fish's liver burned on the coals, into the uttermost parts of Egypt, where the angel bound him.

As'mode'us, The Lame Devil ('Le Diable Boiteux'). A novel by Alain René Le Sage, first published in 1707, and re-published by the author, with many changes and additions, in 1725. It is sometimes known in English as 'Asmodeus,' and sometimes as 'The Devil on Two Sticks,' under which title the first English translation appeared, and was dramatized by Henry Fielding in 1768.

As'monæ'ans, a family of high-priests and princes who ruled over the Jews for about 130 years, from 153 B. C. See MACCABEES.

Asmus, äs'mŭs, **Georg,** a German-American poet: b. Giessen, 27 Nov. 1830; d. Bonn, 31 May 1892. He came to the United States to conduct some mining operations in the copper region of Lake Superior; then lived in New York until 1884, when he returned to Europe. Among the German population of the United States he had an enormous success with his 'American Sketch-Booklet' (1875), an epistle in verse, written in Upper Hessian dialect and overflowing with delicious humor. It was followed by 'New American Sketch-Booklet' (1876). He also wrote 'Camp Paradise' (1877), a story, and a collection of miscellaneous poems (1891).

Asnieres, as-nyār, a northern suburb of Paris, a favorite boating resort with the Parisians. Pop. (1897) 24,317.

Asnyk, äs'nek, **Adam,** a Polish patriot and poet: b. Kalish, 11 Sept. 1838; d. Cracow, 2 Aug. 1897. He participated in the insurrection of 1863, for which he had to spend some years in exile in Germany. He was author of 'Poezye,' (1872–80), and several successful dramas.

Asoka, a-sō'ka, an Indian sovereign, who reigned 255–223 B.C. over the whole of northern Hindustan. He embraced Buddhism, and forced his subjects also to become converts. Many temples and topes still remaining are attributed to him.

Aso'ka (*Jonesia asoca*), an Indian tree, of the natural order *Leguminosæ*, sub-order *Cæsalpineæ*, with a flower, showing orange, scarlet, and bright-yellow tints. It is sacred to the god Siva, and often mentioned in Indian literature.

As'olan'do: Facts and Fancies, the latest volume of poems written by Robert Browning and published on the day of his death, 12 Dec. 1889.

Aso'pus, the name of several rivers in Greece. The most celebrated of this name are those in Achaia and Bœotia.

Asp, a venomous snake. The name as applied in the Bible probably refers to the hooded, or African cobra (*Naja haje*), common in Egypt, and often represented in hieroglyphics. The naja haje is from three to five feet long, and the loose skin on its neck can be dilated into a hood, like that of the Indian cobra, but its markings differ. (See COBRA.) The asp employed for suicide by Cleopatra was probably the small-horned viper (*Aspis hasselquistii*). The asp of southern Europe is *Vipera aspis,* found from France to the Tyrol and in Italy. (See VIPER.)

Asparagin, Asparagine, a nitrogenous substance having the formula $C_4H_8N_2O_3$, or $CONH_2.CH_2CH\ (NH_2).COOH$, occurring in the juice of most plants, and notably in the growing buds of asparagus. It is readily obtained by filtering the plant juice, and evaporating it to a syrupy consistency. The asparagin then separates in the form of trimetric prismatic crystals, which are soluble in water and in acids and alkalis, but insoluble in alcohol or ether. Asparagin undoubtedly plays a very important (though yet

unknown) part in the chemistry of plants, since it occurs in large amounts in germinating seeds, and wherever growth is actively proceeding.

Aspar'agus, a genus of about 150 species of mostly tuberous-rooted, climbing, drooping, trailing, or erect perennial herbs or shrubs widely distributed in tropical and warm temperate countries, especially in southern Europe and southern Africa, but more or less cultivated for food or ornament in all civilized countries. Some species rival and even excel the most delicate ferns in beauty of habit and foliage, which botanically considered, consists not of leaves but leaf-like stems. The ornamental species with the exception of *A. verticellatus* (see below), must all be grown in green-houses, except in southern Florida and southern California, where they may be planted with safety out of doors. They are readily and usually propagated by seeds, but often also by cuttings and by division. Among the best-known ornamental species cultivated in America are the following: *A. medeoloides*, also known as *Myrsiphyllum asparagoides*, the smilax of the florist, is widely grown for decorative purposes, for which its glossy green leaves specially commend it. (For culture, see SMILAX). *A. sprengeri*, a species recently introduced from Natal, with long drooping branches, glossy light-green leaves (white in one variety); small white fragrant flowers in small racemes and little red berries. It is very popular, especially for planting in hanging baskets. *A. plumosus*, a tall climbing species from South Africa with horizontal branches of beautiful form, texture and color, which qualities are retained for weeks or even months after cutting. Deservedly one of the most popular of decorative plants. It has developed several varieties, some of which, especially the variety *tenuissimus*, are even more popular than the original species. *A. verticellatus*, a hardy species with tufts of hair-like leaves and small red berries, is a native of Persia and Siberia, and climbs to a height of 12 to 15 feet from a woody root stock. The stout young shoots are said to be edible, but they quickly become woody and spiny, and are then unfit for the table. Several other species are cultivated for ornament in America.

Best and most widely known, however, is *A. officinalis*, esculent asparagus, which is also used to some extent as an ornamental plant. It is a perennial herb, native of Europe and Asia, and commonly found growing in sandy loam or sea shores, river banks, and among shrubby undergrowth. In a wild state it rarely exceeds a foot in height and a stem diameter of more than one third of an inch; but in gardens sprouts are sometimes obtained as thick as a man's wrist, and the plants often grow more than four feet tall. For more than 2,000 years it has been cultivated for its succulent young shoots, produced from the thick root stocks in spring. An excellent method of growing the plant may be epitomized as follows:

The land chosen for the bed should be a rich, friable and warm loam, preferably exposed to the south or east. Manure should be applied without stint before the plants are set, and the preparation of the soil should be deep and thorough. The plants may be home-grown or purchased. One-year-old plants, if sturdy, are preferable to older ones. For home growing a separate nursery bed should be prepared, and the seed previously soaked 24 hours in order to hasten germination, when sown in early spring, about two inches apart and one inch deep, at which rate an ounce should be enough for 200 or more feet of drill. Some radish seed of a small early maturing variety should be sown in the same drill, so that the young radish plants, which quickly appear, may mark the position of the rows of the slower-appearing and less-conspicuous asparagus plants. As soon as the radishes are of edible size, or even before, if necessary, they should be pulled and the asparagus plants, then an inch or two tall, left in possession of the ground. Beyond keeping down weeds, destroying pests, and thinning the plants to four inches asunder, no further attention is necessary during the first year. In the spring of the second year, if properly managed during the first, the plants should be large enough to be transplanted to the permanent bed. If too small they should be transplanted at least eight inches asunder, and grown a second year in a nursery bed. In the permanent bed the plants should stand at least two feet asunder in rows not less than four feet apart. Five or even six feet for the larger growing varieties is much better. Staminate plants are more productive of shoots than pistillate, but are difficult to recognize until the plants flower. The furrows are plowed six inches deep or deeper, the plants set in the bottom, but at first covered with only about two inches of earth. After growth starts the trench is gradually filled by cultivation which must be thorough, both among the plants and between the rows. Not before the second spring after planting in permanent quarters should any shoots be gathered. At the time of planting a liberal dressing of some slowly decomposing fertilizer, such as ground bone, should be given in the drill, and in the spring of each year complete fertilizers should be applied liberally. (See FERTILIZERS.) In addition to such applications many growers spread stable manure upon the bed in the autumn after the tops have been removed, a necessary practice to prevent the scattering of the seeds upon the bed. In the spring as soon as the soil can be worked the land is either plowed shallow or cultivated deeply to bury the manure. Since the plants are gross feeders there need be little fear of fertilizing too heavily. Methods of gathering depend somewhat upon whether the stalks are to be blanched or left green. Blanching is done by ridging the soil 13 inches deep above the crowns. Stalks so produced are gathered as soon as the tips appear above the soil; green stalks are cut when about nine inches long, including the base of two or more inches below the surface of the ground. In each case the stalk may be cut with an asparagus knife or preferably snapped near the crown, or at least at the proper depth, if blanched, by plunging the hand down in the loose soil beside the stalk and severing it with the fingers. By the latter method there is less danger of injuring other shoots. All cutting should cease when green peas, grown in the same locality, are ready for the table, because the plants must be given opportunity to store up food for the following year. The stems are usually sold in bunches of various sizes, the grade depending upon the length and

number of stalks in the bunch. The bunch commonly sold is eight and one half inches long, weighs about two pounds, and contains 30 spears. As a rule, the thicker the spear the better. First class spears are three quarters of an inch thick or thicker. Every care must be taken in handling to prevent bruising, since a gummy juice collects in the broken cells, and the injured stalks spoil by heating. After washing, the stalks should be dried and kept cool. If to be shipped long distances, their butts should rest in damp sphagnum moss or similar material. In the home garden, where horse cultivation is not practicable, the plants may be set even as close as 18 inches by two feet, but the manuring, cultivation and other care must be increased in order to obtain choice shoots. Each spring the very liberal dressing of manure applied the previous autumn should be forked, not dug, in, and a lavish amount of commercial fertilizer, rich in potash, phosphoric acid, and nitrogen, applied. Soap suds may be emptied upon the bed; they have more or less potash in them. Asparagus sometimes is forced in hot beds, under greenhouse benches, in cellars, etc., by setting mature crowns (plants) close together and supplying heat and moisture. A large amount of light is not essential. It is also forced in the field by covering the beds with cloth and applying heat by means of portable steam pipes, either in or upon the ground. In the former case the roots are ruined by the process; in the latter, they are not, but should be given one or more years to fully recuperate. (See reports and bulletins of Cornell Experiment Station and of Missouri Experiment Station). Several other species furnish edible shoots; for example, *A. acutifolius, A. albus* and *A. tennuifolius,* all European species. The tubers of *A. lucidus* are eaten in China and Japan, where the species is indigenous. The shoots of *A. scaber,* which resemble those of *A. officialis,* are inedible because bitter.

Enemies.— Asparagus has only two important enemies, and when compared with other general crops, long cultivated, only a few less serious ones. Asparagus rust (*Puccinia asparagi*) has been known for about 100 years, but only during the last decade of the 19th century did it do serious damage. In a badly infested field the plants as a whole seem to be maturing very early, their deep green having been replaced by a tawny brown. The stems examined closely, show a blistered and ruptured skin, beneath which are brown masses of spores or in late autumn, almost black winter spores. In the spring the «cluster cup» is the form observed. The most effective control is the resin-Bordeaux mixture, made by adding to each 48 gallons of standard Bordeaux mixture two gallons of resin stock solution, made as follows: Heat five pounds of resin and one pint of fish-oil in a kettle until the resin is dissolved. If very hot, allow to cool somewhat. Then slowly stir in one pound of potash lye and heat again till the mixture becomes the color of amber, when five gallons of water must be added. If the potash be added while the resin is too hot, the mixture may ignite. This solution increases the adhesiveness of Bordeaux mixture. (See FUNGICIDE.) With the mixture 50 per cent greater yield has been obtained in unfavorable seasons, and 70 per cent in favorable. Growers cutting 800 bunches or more per acre find that thorough spraying each week for four, five or even more weeks pays well. For detailed account of this disease and specific methods of control, see New York Experiment Station Report (1901). The asparagus beetle (*Crioceris asparagi*), a European insect introduced about 1856, the only seriously injurious insect pest, is about one quarter of an inch long with black and yellow or red wing-covers. It belongs to the *Chrysomelidæ.* It appears as the adult in spring, and lays eggs on the shoots. In a few days grayish-green grubs appear and gnaw the green parts of the plants. When full grown they burrow in the ground to pupate for a short time. The broods succeed each other at intervals of about a month, if the weather be favorable. Their natural enemies are lady-bird beetles and soldier beetles. The popular remedies are the corralling of chickens, ducks, and turkeys in the plantation; cutting all volunteer plants in waste places; cutting new shoots daily; allowing spindling shoots to remain in alternate rows for the insects to deposit their eggs upon and burning the shoots not less often than once a week; dusting with air-slaked lime or road dust while the dew is on; brushing the grubs to the hot ground from the full grown plants, the middle of the day being chosen for this operation; spraying with arsenites, hellebore or other stomach poisons; etc. A case of fight early and fight late! The 12-spotted asparagus beetle (*Crioceris 12-punctatus*), about the same size as its relative just described, but orange red with black dots, has a similar life history, and may be controlled in the same way but is not yet seriously troublesome, except in a few localities. Several plant bugs, moth larvæ, beetles and aphids also feed upon asparagus, but have not become serious pests. Consult: Year-book United States Department of Agriculture (Washington, 1896), and Bulletin No. 10 (1898). See INSECTICIDES.

For fuller details of asparagus culture consult: Hexamer, 'Asparagus Culture' (1901); Bailey and Miller, 'Cyclopedia of American Horticulture' (1900–02). In the latter will also be found specific instruction for the cultivation of ornamental asparagus.

Asparagus-stone, a variety of apatite, found in Murcia, Spain, in the form of small, transparent, yellowish-green crystals.

Aspasia, ăs-pā'shĭ-a, a celebrated woman of ancient Greece: b. in Miletus in Ionia, but spending a great part of her life in Athens. Her house was the general resort of the most virtuous, learned, and distinguished men in Greece. She inspired the strongest and most enduring affection in the heart of Pericles, who had separated from his own wife and united himself to Aspasia as closely as was permitted by the Athenian law, which declared marriage with a foreign woman illegal. When the Athenians were dissatisfied with Pericles, instead of attacking him they persecuted the objects of his particular favor, and accused Aspasia of contempt of the gods. Pericles defended her in the Areopagus, but it required all his influence to procure her acquittal. After his death (B.C. 429) Aspasia is said to have attached herself to a wealthy but obscure cattle-dealer, of the name of Lysicles, whom she soon made, however, an influential

citizen in Athens. She had a son by Pericles, who was legitimated by a special decree of the people.

As'pect, a term in astronomy and astrology, denoting the situation of the planets and stars with respect to each other. There are five principal aspects: (1) sextile aspect, when the planets or stars are 60° distant, and marked thus, *; (2) the quartile or quadrate, when they are 90° distant, marked □; (3) trine, when 120° distant, marked △; (4) opposition, when 180° distant, marked ☍; and (5) conjunction, when both are in the same degree, marked ☌. Kepler added eight more. It is to be observed that these aspects, being first introduced by astrologers, were distinguished into *benign, malignant,* and *indifferent;* and Kepler's definition of aspect, in consequence, is "Aspect is the angle formed by the rays of two stars meeting on the earth, whereby their good or bad influence is measured." The aspects now in use are conjunction, opposition, and quadrature.

As'pen, Col., a city and county-seat of Pitkin County, on the Roaring Fork of Grand River, and the Colorado Midland, and the Denver & R. G. R.R.'s; 30 miles west of Leadville. It was incorporated in 1883; and has since become the centre of one of the richest mining sections in the country. In the city and vicinity are more than 20 mines, for which there are a number of silver, zinc, and lead ore mills. While the smelting and concentrating of ores is the distinctive industry, the city has several minor factories, and it is also the principal mining trade centre of the Roaring Fork Valley. Pop. (1900) 3,303.

As'pen, tremulous poplar, a tree of the order *Salicaceæ* and genus *Populus*, native of the cooler parts of Europe and Asia, and succeeding best upon moist, gravelly soils. It grows quickly; usually attains a height of 50 to 60 feet, sometimes even 100 feet; has light, small, thin-toothed leaf-blades upon long, slender, flattened petioles which permit the blade to flutter with the least breeze, hence the specific name *P. tremula*, tremulous. The wood being white, light, soft, and porous, is not a valuable fuel, but is useful for making charcoal for the manufacture of gunpowder, and for turning, often being employed for making bowls, trays, troughs, and pails. The wood may be made harder and thus rendered useful for interior work in houses by peeling off the bark and allowing the stem to dry before felling it. In places where this tree abounds, and other timber is scarce or expensive, this method of hardening is very useful. The bark is rich in a glucoside called salicin and used in leather tanning. In the United States the tree is best known as an ornamental one, its variety, *pendula*, with graceful drooping sprays, being perhaps the best weeping poplar. The male plants are preferred because of the abundance of their catkins which appear in early spring before the catkins of American species blossom. The American aspen (*Populus tremuloides*), very generally distributed from Alaska to Labrador and southward to Pennsylvania and California, and, in the mountains to Mexico, so closely resembles the preceding species that many botanists consider it merely a variety. Its light-gray branches render it conspicuous in clearings where it is one of the first trees to appear. It is said to attain a height of 100 feet when grown in the forest. This tree, like the following, is widely used in the manufacture of wood pulp. The large-toothed aspen (*Populus grandidentata*) is a large American species found from Nova Scotia to Minnesota and southward to Tennessee. It is a tall tree, often reaching 75 feet, and has bluish or rusty-white leaves thicker and larger and with more spreading teeth than the former two species. Except its drooping varieties, it is rarely used as an ornamental tree. See POPLAR.

Aspern, äs-pern, and **Esslingen,** two villages a few miles east of Vienna, on the opposite bank of the Danube, celebrated for the battle fought 21 and 22 May 1809, between the Archduke Charles and Napoleon I. After the fall of the capital the Austrian general resolved to suffer a part of the enemy's forces to pass the Danube, and then to surround them with his own army and drive them if possible into the river. Everything depended on the possession of these two villages: Aspern was at first taken by the Austrians, again lost and retaken, till they at length remained masters of it: from Esslingen they were continually repulsed. The battle was renewed on the 22d; the French army being now increased so as at least to equal the Austrians in number. Thousands of lives were sacrificed in vain attempts to capture the villages. Aspern continued to be the stronghold of the Austrians and Esslingen of the French. When the army of Napoleon gave up all hopes of gaining the victory by forcing the centre of the Austrians, Esslingen served to secure their retreat to the island of Lobau. The loss of the Austrians in killed, wounded, etc., was estimated at less than a third of the whole army; that of the French at half. The latter lost on this occasion Marshal Lannes. The Austrians had 4,000 men killed and 16,000 wounded, the French 8,000, 30,000 wounded. By the French the engagement is known as the battle of Essling or Esslingen, but the Austrians style it the battle of Aspern.

Asphalt. The general term asphalt is applied to the several varieties of hydrocarbons of an asphaltic base which exist in all conditions from the liquid to the solid state. It is more specifically employed to include the purer forms of hard and soft bitumen, such as elaterite, albertite, gilsonite, nigrite, wurtzilite, brea, etc. The term bituminous rock includes sandstones and limestones impregnated with bitumen or asphalt. This rock, usually shipped without previous refining, is used principally for street pavements and is mixed with other ingredients at the place of use.

The importation of asphalt into the United States is chiefly from the Island of Trinidad, off the coast of Venezuela. Other imports are made from Bermudez and Venezuela. Bituminous limestones are imported from Neuchatel and Val de Travers, in Switzerland, from Seyssel in France, and in small quantities from Germany, Italy, Russia, Austria-Hungary, Spain, Turkey in Asia, Great Britain, the United States of Colombia, Canada, the Netherlands, Cuba, and Mexico. The total imports from Trinidad and Venezuela in 1900 amounted to 134,189 long tons, and at the present time the value of our

domestic product is about equal to that of the imported asphalt, at the point of shipment. The Island of Trinidad, one of the British West Indian possessions, is, next to France, the largest producer of asphalt in the world. The deposits are operated by an American corporation under a concession from the British government, and, also, independently, from land not belonging to the crown, acquired by purchase. The chief source of supply is a lake of pitch filling the crater of an extinct volcano. This lake lies 138 feet above sea-level, and has an area of about 114 acres. The supply is partly renewed by a constant flow of soft pitch into the centre of the lake from subterranean sources. The shipments of this lake pitch average over 80,000 tons per year, and the flow into the lake is at the rate of about 20,000 tons per year. The depth of this lake is about 135 feet at the centre. Distinct from the lake pitch is what is known as "land pitch," the overflow in past times of pitch from the lake, and deposits of similar nature. During recent years strenuous efforts have been made to discredit all asphalt mined from properties located outside of Pitch Lake. These efforts seem to have failed, however. Careful analyses of samples of asphalt taken from different parts of Pitch Lake, from deposits outside the lake and from the district of La Brea show that these asphalts are so similar in composition that for practical purposes they may be considered as identical in quality. The samples have a common origin, for the presence of mineral matter in these asphalts cannot be regarded as adventitious, since it is thoroughly incorporated with the bitumen in the same proportion and has the same percentage of composition, as regards the relative proportions of matter soluble in water, in acids and insoluble substances. There is no doubt that the pitch found in the deposits outside the lake has been divided from the lake itself by the subterranean flow of pitch to the viscous condition, a condition rarely assumed under the combined influence of heat and pressure. It is true there is a difference in the crude materials in these asphalts; one is softer than the other, because of containing more volatile oils. Nature simply began on the asphalt outside the lake; it being more exposed to the rays of the tropical sun, the process of refining it drove those volatile oils off, a necessary accomplishment to make the material fit for paving purposes. It would appear, therefore, that a part of the labor of refining has been done on the land or overflow asphalt which remains to be done with the lake asphalt.

In 1875 the asphalt paving industry was in its infancy in the United States. In 1903 there were about 42,000,000 square yards of asphalt, sheet and block, which has been laid at a cost of about $110,000,000. These pavements are frequently called bituminous pavements, inasmuch as bitumen is the largest constituent of the asphalt, frequently running as high as 9 per cent. Asphalt is manufactured into a cement by mixing it with other forms of bitumen, and this cement is in turn used to bind together particles of sand and limestone in the asphalt pavement. No two asphalts are alike. The life of the pavement depends upon the crude bitumen used, the skill in its manufacture into bituminous cement, the proper proportioning and mixing of the cement with the sand and dust and in the selection of the mineral aggregate.

In 1870, Prof. E. J. Smedt, a Belgian chemist, laid the first sheet asphalt pavement in this country, in Newark, N. J. Prior to this date, coal tar had been used as the cementing material, but with little satisfaction. In 1876 Congress appointed a commission, consisting of Gens. Horatio G. Wright and Quincey A. Gilmore, of the corps of engineers, and Edward Clark, architect of the capitol, to select the best pavement for Pennsylvania Avenue in Washington. Forty-one proposals, for stone, macadam, tar and asphalt pavements, were received. The commission selected two, and decided to use Neuchatel rock asphalt, and De Smedt's artificial Trinidad mixture, in the proportion of two to three. The artificial Trinidad mixture has been most satisfactory. When it was decided, in 1889, to repave Pennsylvania Avenue in Washington, the entire avenue was relaid with it, and the Neuchatel was discarded.

Trinidad Pitch Lake has furnished over 85 per cent of the asphalt used in the United States. The liquid asphalt passing through clay saturates it or carries it in suspension and becomes a brown, earthy, non-viscous substance, chemically composed as follows:

Bitumen	47 per cent
Infusorial earth	28 per cent
Water	25 per cent

The water is evaporated in refining and the residue (approximately one third clay and two thirds hard asphalt) regains some of its viscosity and requires the admixture of some flux or softening agent to give it the proper consistency for paving operations. Samples taken at 100 and 150 feet deep at the centre of Pitch Lake do not differ in composition from those taken on the surface near the shore, showing the homogeneousness of the entire mass. The surface is in constant motion, and gradually lowers as the asphalt is removed. Refined asphalt is shipped from Trinidad to Mexico, South America and other foreign countries; but, owing to the very high duty on refined asphalt coming into the United States, it is cheaper to refine here.

In 1892, the New York and Bermudez Company began the importation of a very pure and hard asphalt from a deposit in the State of Bermudez, Venezuela, and up to the present time about 3,000,000 square yards of pavement have been laid with this material. The Bermudez Asphalt Lake, covering an area of about 1,000 acres, lies about 20 miles from the Gulf of Paria, in a straight line. There are many springs of soft asphalt or maltha, the largest being about 7 acres in area. Outside of the springs, where new material is constantly exuding, the surface of the lake is covered with vegetation and trees, which must first be cut off to reach the asphalt. The quality of the asphalt varies from maltha or liquid asphalt exuding from the springs, to a hard glance pitch. The crude Bermudez asphalt contains on an average about 31 per cent of water, which is present as a mixture and not as an emulsion, and about 66 per cent of bitumen. This asphalt is softer and more brittle than Trinidad, but possesses all essential cementitious qualities.

As early as 1879 asphalt found in Southern California was laid at an intersection on Market Street, San Francisco, which is the heaviest traveled street in that city. In 1884 the late Jesse Warren reported on these California

asphalts, the only indications of which were slight surface exudations of liquid asphalt and large banks of bituminous sandstone (sand saturated with asphalt). In 1895, the Alcatraz Company successfully laid two streets in New York city and acquired a high standing for the California product which was subsequently controlled by the Asphalt Company of America. It has been laid in many Eastern cities, under the trade name of "Alcatraz," "Standard," "Ventura," etc., and has been uniformly successful when refined, mixed and laid intelligently, by men experienced in handling asphalt in all its stages. Shortly after the organization of the Asphalt Company of America, beds of very pure, high grade, liquid asphalt were discovered in Southern California. This being a nearly pure, viscous bitumen, it does not require a softening agent or flux, nor the admixture of other bituminous material, to make it of the proper consistency for paving.

Asphalt Painting. Asphalt was once largely used in painting, especially in the old Dutch school. It was dissolved in spirits of wine to ensure greater permanence. Because of its unreliability it ceased to be used.

Asphalt Process, a photographic process devised about 1814 by J. N. Niepce (q.v.). He coated a plate of polished metal with asphalt varnish, and then placed it with a drawing in a camera obscura for from 4 to 6 hours. The parts of the asphalt which had been acted upon by the light became insoluble. The parts of the asphalt film that had been protected were dissolved by essential oils, and thus a copy of the drawing was brought out. The "heliographs" thus made were not particularly successful. This method has been modified in the asphalt process of photo-mechanical printing. See PHOTO-ENGRAVING.

Asphaltic Coal, coal-like substances which though they have sometimes been classified as coals, differ from all the true coals in respect to both their geological position and their composition. They do not occur in strata, but occupy cavities and fissures, into which they appear to have flowed when plastic. They have been found in Devonian, Carboniferous, and Tertiary rock. The regions in which they are principally mined are Albert County, New Brunswick (albertite), the Uinta Mountains, Utah (gibsonite and uintahite), and Colorado, West Virginia, Texas, and Mexico (grahamite). Wurtzilite is found also in Utah. Their chief uses are as a basis for varnishes, and as insulators. Consult: Blake, 'Uintahite, Albertite, etc.'; 'Transactions' of the American Institute of Mining Engineers, Vol. XVIII. (1890).

As'phodel, a small genus, *Asphodelus,* of hardy annual and perennial fleshy-rooted herbs, natives of the Mediterranean region, belonging to the natural order *Liliaceæ,* but by some botanists made the type genus of the natural order *Asphodelæ. A. luteus, lutea,* king's spear, or yellow asphodel, the true asphodel of the ancients, attains a height of two to four feet, has numerous long (3 to 12 inches) narrow rough-margined leaves which embrace the stem, and in early summer yellow flowers in long racemes (6 to 18 inches), and large persistent membranous bracts. *A. albus,* branching or white asphodel, which has radical leaves, blossoms about the same time as the preceding species, and produces its white funnel-shaped blossoms in branched clusters. Both species are readily propagated by division and are of easy cultivation in any soil. They thrive fairly well in partial shade, but do better when more or less exposed to the sun. *A. ramosus,* a species which by some botanists is made to include *A. albus* and many other species, is cultivated in Algeria and some other countries for its starchy roots which are used to make alcohol. The refuse from this manufacture, together with the leaves and stems, is employed in paper and cardboard-making. Several other related plants are often called asphodel, among which are *Narthecium ossifragum,* bog asphodel, common on European moors; *N. americanum,* by some botanists considered a form of the preceding, and *A. californicum,* similarly called in America. False asphodel is a name given to several species of *Tolfiedia.* The asphodel of the poets is *Narcissus pseudo-narcissus.*

Asphyxia, etymologically, pulselessness, but literally a condition of partial or complete loss of consciousness because of defective oxidation of the blood. The symptoms may be developed rapidly or slowly. In sudden occlusion of the air passages, such as caused by a foreign body in the larynx, or compression of the throat as in hanging, there is usually a quiet period of from 20 to 30 seconds after which respiratory movements, both of inspiration and of expiration, follow. These gradually increase in frequency and depth until in about a minute powerful expiratory convulsions occur; convulsive movements of inspiration are also produced, but these are usually milder in character. A period of exhaustion sets in, the respiratory movements become slower and more irregular, and gradually cease. During this period the face has become pallid, and then deeply cyanosed and flushed, the lips blue to purple, and the body temperature, at first increased, gradually diminishes. The blood pressure is at first increased, and then falls gradually to zero. Unconsciousness develops about a minute after the occlusion, although there is great individual variation, the sphincters relax and the urine and fæces are passed. There is a loss of muscle-tone, and the reflexes are abolished. In asphyxia both lack of oxygen and increase of carbonic-acid gas in the blood are important factors. Asphyxia may result from an excess of carbonic-acid gas with a normal amount of oxygen, and may be produced, if the amount of oxygen is diminished one half, with no variation of the carbon dioxide. For treatment, see DROWNING.

As'pic, a dish consisting of a clear, savory meat jelly, containing fowl, game, fish, etc.

Aspid'ium, a widely distributed genus of ferns, numbering upward of 500 species, of which more than a dozen are found in the United States, including the male and shield ferns. Their only economic use is in medicine. The active principles in this and allied species are filicic acid, aspidin and other phloroglucin-like bodies. The action is largely on the tapeworm, for which parasite this drug is given. Poisonous symptoms sometimes are produced. These are pain, muscular weakness, purging, collapse, and even death. Temporary blindness has been produced by male fern.

As'pinwall, William, an American physician: b. Brookline, Mass., 23 May 1743; d. 16 April 1823. He studied medicine in Philadelphia, and practised in his native town. He served as surgeon with the Revolutionary army, and later became interested in the subject of vaccination and established that preventive in American practice.

As'pinwall, William H., an American constructor of railroads: b. New York city 16 Dec. 1807; d. 18 Jan. 1875. He was for many years a partner in a large shipping firm in New York, but retiring from it in 1850, turned his attention to building the Panama Railroad, whose eastern terminus of Aspinwall is named in his honor. He was likewise prominent in forming the Pacific Mail Steamship Company.

Aspiroz, as-pē'rōth, **Manuel de,** Mexican soldier, statesman, and diplomat: b. Puebla 9 June 1836; d. Washington, D. C., 24 March 1905. He graduated from the University of Mexico in 1855, was licensed to practise law in 1863, but upon the French invasion entered the army. In the Juarez insurrection of 1863 against Maximilian, he served in the insurgent army with great distinction, rising from 2d lieutenant to colonel. After the fall of Queretaro he was appointed judge-advocate of the military court which sentenced the emperor to death, thereby incurring the lasting hatred of the imperial house of Austria, of which Maximilian was a member. In 1867 Aspiroz became assistant secretary of state for foreign affairs in the new republic; in 1872 did much to settle amicably the claims between the United States and Mexico, which dated from the Mexican war in 1845; in 1873–5 was consul at San Francisco; and in 1875 was elected senator from his native province to the Mexican national congress. In 1881 he left the senate to become a member of the commission appointed to make treaties with the powers of the world; was law professor in the College of Puebla from 1883 to 1890, when he was again appointed by President Diaz assistant secretary of state, serving in that capacity until appointed, in 1899, first Mexican ambassador to the United States, a position he held till his death. In 1900 he was the Mexican representative at the Hague tribunal; was a member of several scientific organizations, a knight commander of the military Order of Our Lord Jesus Christ of Portugal, and had been presented by the Shah of Persia with the decoration of the Order of the Lion and Rising Sun, and by the dowager empress of China with the insignia of the Order of the Dragon, in both cases in appreciation of his services in negotiating treaties between their respective countries. He published: 'Código de extranjeria de los Estados Unidos Mexicanos' (1876); and 'La libertad civil como base del derecho internacional privado' (1896).

Asple'nium, a genus of about 200 species of small ferns of world-wide distribution, belonging to the sub-order *Polypodiaceæ*, characterized by free veins and elongated sori covered by an indusium. Many of the species are very beautiful and are consequently favorites with cultivators whose space is limited. *A. viride*, *A. adiantum-nigrum*, *A. trichomanes*, and other species are commonly called spleenwort from their formerly supposed efficacy in internal medicine. The two last-mentioned species also bear the name of maiden-hair, but are not the true maiden-hair fern (*Adiantum*). In the eastern United States a dozen or more species are to be found growing wild, among which the more common are *A. thelypteroides*, *A. angustifolium* and *A. felixfœmia*, which reach a height of from one to four feet. In cultivation, slight shade is almost essential, as is also abundant water at the roots, but the air must not be very moist else the leaves will turn brown. The plants thrive in peaty soil. See FERNS.

As'quith, Herbert Henry, an English statesman: b. Morley, Yorkshire, 12 Sept. 1852, and educated at Balliol College, Oxford. He studied law and was admitted to the bar of Lincoln's Inn in 1852. He entered Parliament in 1886 as member for East Fife, and was re-elected in 1892 and in 1895, and was home secretary in Gladstone's last cabinet. He was conspicuous as a debater during the Home Rule discussions, and in 1894 drew up the Welsh Church Disestablishment Bill. In December 1905 he was appointed Chancellor of the Exchequer in the Liberal cabinet of Sir Henry Campbell-Bannerman.

Ass (As. *assa*, Goth. *asilus*, Rus. *oselu*, Lat. *asinus*, probably of Eastern origin; cf. Heb. *āthōn*, she-ass) or, when domesticated, DONKEY. A member of the family *Equidæ* and usually placed in the genus *Equus*, with the horse, though sometimes made the type of a separate genus *Asinus*. There are at least three species, one Asiatic, and the others African. From the North African species the domesticated ass or donkey has probably descended, although many of its characteristics, particularly its spirit and bearing, are greatly altered. In size, in the short hair and terminal tuft of the tail, and in the fact that only the fore-legs present callosities, the ass resembles the zebra rather than the horse; and although not striped like the zebra, it has a varying tendency to stripes on the legs. The Asiatic ass (*Equus hemionus*) is divided into three local varieties, of which the one found in Persia and Syria must be that which the Old Testament writers used as a type of unhampered wildness. Of the others, the kiang, koulan, or dziggetai of Thibet, is the largest and most strikingly colored. Its height is sometimes four feet at the shoulders. Like all asses, it is pale underneath, but the color above is a dark red with a narrow black stripe along the mane and backbone from head to tail. The third variety, the onager or ghorkhar, like the first, is smaller and paler; sometimes it is even silvery, and its dorsal stripe is broader in proportion than that of the Thibetan ass. It inhabits the plains of northwestern India, Afghanistan, and Beluchistan. Unlike the donkey, these wild asses are so extremely swift, enduring, and agile that on the plains they cannot be overtaken by a single horseman. In the mountains they are less shy, and sometimes voluntarily approach travelers. Wild asses are hunted for sport, and it is said of their flesh, that, while resembling venison, it has an even finer quality. The asses of the plains migrate to the hills in summer when the plains are dry. See KIANG; ONAGER.

The African ass (*Equus Africanus*) differs widely from the Asiatic, being larger and having a bluish tint rather than a tendency to red.

It is sometimes as much as 14 hands high, and has the very large ears which characterize the donkey. The dark stripe on the back begins only at the shoulder, but extends from the tail down the withers; the hair of the mane and tail is short, and varies little from that of the body in color. It is found in all the open regions of northeastern Africa, and westward through the Sahara and Sudan. Like the Asiatic ass, it is extremely wild and fleet. A second species of African wild ass (*Equus somalicus*) was found in Somaliland a few years ago (see Proc. Zool. Soc. of London, 1884, p. 540), which is distinguished by its grayer color, and faintness of its stripes; it also has smaller ears and a more flowing mane. Living examples have been kept in London.

The leading authorities on these animals are Blanford and Tegetmeier, the latter the author of 'Horses, Asses, and Zebras' (1895).

The donkey, or domestic ass, was probably first tamed in Egypt, where it was known before the horse, and has always been much used; some of the Eastern breeds of the donkey are far larger and finer than those commonly seen in Europe, though in Spain and Italy, where they are more used, they are superior to those of other European countries. In England they are little employed, but in America are kept by stock raisers in the Middle and Southern States for the breeding of mules and hinnies. (See MULE.) Their milk is recommended in cases of consumption and dyspepsia, and their skins furnish the leather called shagreen, besides an excellent shoe-leather and the covering of drums.

Ass, Feast of the, a mock ceremony observed in northern France in the Middle Ages. It was originally a good-natured parody on the church service without intentional irreverence, but degenerated into an indecent performance. It was in substance a brief farce in which Balaam's ass appeared before the church altar to prophesy the coming of Christ.

Assab, as-säb', an Italian trading station on the coast of the Red Sea, 40 miles from the Strait of Bab-el-Mandeb. The neighboring district with an area of 243 square miles, was sold in 1870 by some Danakil chieftains to an Italian steamship company for a coaling station on the road to India. In 1880 it was taken over by the Italian government, which, since 1884, has improved the harbor and erected a lighthouse.

Assai, as-sī', a food made from the fruit pulp of various species of Brazilian palms closely allied to the cabbage palm (q.v.) and largely used in the lower Amazon region. The principal species are *Euterpe edulis* and *E. Catinga*. The first species grows in tide-flooded swamps, where it may attain a height of 90 feet with a diameter of only four or five inches. It produces upon branched spadices an abundance of small pea-like purple fruit with a thin firm pulp and a hard seed. These fruits are kneaded in warm water to produce the thick purplish assai which is generally eaten with starchy foods. The terminal bud of this species is eaten like that of its close relative, *E. oleracea*, the cabbage palm, and its stems are used as rafters and poles. The other species grow on dry, sandy, upland soils, its smaller quantity of fruit furnishing a sweeter assai.

Assal, as-säl', a large salt lake in the district of Adal, in eastern Africa, near the coast of the Bay of Tajura. It is nearly 600 feet below the level of the sea. Abyssinian caravans resort to Assal for the purpose of carrying off the salt, thickly encrusted on its shores.

Assam', a chief-commissionership of British India, situated mainly between Upper Burma and the Himalayas, with an area of 52,078 square miles. It may be considered as a long series of fertile valleys watered by the Brahmaputra and its tributaries. The valley of the Brahmaputra consists of rich alluvial plains, either but little elevated above the flood-level of the Brahmaputra and its feeders, or so low that large extents of them are flooded for three or four days once or twice in the year. The Surma valley is even more subjected to inundations than the plains of the Brahmaputra, but the Surma and its tributaries having more permanent banks, the shifting is trifling compared with the banks of the Brahmaputra. In Assam are found the valuable teak and sissoo trees, date, and sago palms, the areca palm (the betel-nut-tree), the Indian fig tree, etc. But the article of most commercial importance grown in Assam is tea. The plant was discovered growing in this region in 1823, but not till 1838 did the first shipment reach England. The plant producing it, though not regarded as specifically distinct from that of China, is much larger and more vigorous. There are now about 300,000 acres under tea; the yield is about 100,000,000 pounds annually. Rice covers a large extent of the cultivated soil, occupying about 1,500,000 acres. The other crops include maize, pulse, oil-seeds, sugar-cane, hemp, jute, potatoes, etc. In the jungles and forests roam herds of elephants, in the dense and swampy parts of the forests the rhinoceros is met with, and tigers and wild buffaloes abound; leopards, bears, and wild hogs are numerous, and among other animals are jackals and foxes, goats, deer, and the venomous cobra. Coal, petroleum, limestone, and iron are found, and gold-dust is met with in many of the rivers. The coal-beds are supposed to be co-extensive with the main valley, but coal is only worked to the south of the Brahmaputra. The inhabitants are mostly engaged in agriculture. There is no Assamese nation proper, various ethnical groups being represented. The people seem to be contented, good-natured, and indolent, and have few wants beyond what can be easily supplied from their fertile fields, for which they pay but a very small rental. Great respect is paid to the aged; parents, when no longer able to work, are supported by their offspring; they are tenderly attached to their children, kind to their relatives, and hospitable to people of their own caste. Assam, known in ancient Indian history as Kâmarûpa, formed in the 7th century A.D. a powerful independent kingdom under a Brahman sovereign, but in the 15th century it broke up into 12 separate states, which, in spite of their numerous internal struggles, were generally able to resist the attacks of the powerful Mogul emperors. Late in the 18th century its condition encouraged the Burmese to make the country a dependency of Ava, but the Burmese encroachments on the territory of the East India Company brought about war with the British. In 1826 Assam became a possession of Great

Britain under the administration of the lieutenant-governor of Bengal, and in 1874 was erected into a chief-commissionership. There are no towns properly so-called, but some large villages. The seat of administration is Shillong. Pop. (1901) 6,122,201.

Assas, äs'sä, **Nicolas, Chevalier d'**, a French officer, celebrated for an act of patriotism which cost him his life. He was captain in the regiment of Auvergne when the French army was stationed near Gueldres, in 1760, and on 15 October, while engaged in reconnoitering, was taken prisoner by a division of the enemy advancing to surprise the French camp, and threatened with death if a word escaped him. He shouted, "*A moi, Auvergne, voila les ennemis!*" and was instantly struck down. An annual pension was allowed to his descendants.

Assas'sina'tion, a term denoting the murder of any one by surprise or treachery. It is commonly applied to the murder of a public personage by one who aims solely at the death of his victim. In ancient times, assassination was often even applauded, as in the Scriptural instances of Ehud and Jael, and in the murder of Hipparchus by Harmodius and Aristogeiton; but assassination by enthusiasts and men devoted to an idea first became prominent in the religious struggles of the 16th and 17th centuries. To this class belong the plots against the life of Queen Elizabeth; while the succession of assassinations of Roman emperors is but a series of murders prompted by self-interest or revenge. Omitting these last, the following list includes the most important assassinations, arranged in chronological order. Fuller accounts of the persons mentioned will be found under their particular headings:

Philip of Macedon		B.C.	366
Julius Cæsar	Mar. 15	B.C.	44
Thomas Becket	Dec. 29,	A.D.	1170
Albert I. Emperor of Germany	May	1,	1308
James I. of Scotland	Feb.	21,	1437
Alessandro de Medici	Jan.	5,	1537
Cardinal Beaton	May	29,	1546
David Riccio	Mar.	9,	1566
Lord Darnley	Feb.	10,	1567
James, Earl of Murray, Regent	Jan.	23,	1570
William of Orange	July	10,	1584
Henry III. of France	Aug.	1-2,	1589
Henry IV. of France	May	14,	1610
Villiers, Duke of Buckingham	Aug.	23,	1628
Wallenstein	Feb.	25,	1634
Archbishop Sharp	May	3,	1679
Gustavus III. of Sweden, Mar. 16; d.	Mar.	29,	1792
Marat, by Charlotte Corday	July	13,	1793
Gen. Kleber at Cairo	June	14,	1800
Paul, Czar of Russia	Mar.	24,	1891
Spencer Perceval, premier	May	11,	1812
Kotzebue, the dramatist	Mar.	23,	1819
Duc de Berri	Feb.	13,	1820
Charles III., Duke of Parma, Mar. 26; d.	Mar.	27,	1854
President Abraham Lincoln, April 14; d.	April	15,	1865
Michael, Prince of Servia	June	10,	1868
Marshal Prim, Dec. 28; d.	Dec.	30,	1870
Georges Darboy, Archbishop of Paris	May	24,	1871
Earl of Mayo, governor-general of India	Feb.	8,	1872
Sultan Abdul-Aziz	June	4,	1876
Alexander II., Czar of Russia	Mar.	13,	1881
President James A. Garfield, July 2; d.	Sept.	19,	1881
Lord Frederick Cavendish and T. H. Burke, in Phœnix Row, Dublin	May	6,	1882
President Sadi Carnot, France	June	24,	1894
Ex-Premier Stefan Stambuloff, Bulgaria, July 15; d.	July	18,	1895
Premier Canovas del Castillo, Spain	April	22,	1897
President Juan Idiarte, Uruguay	Aug.	25,	1897
Empress Elizabeth of Austria, in Geneva	Sept.	10,	1898
President Ulisses Heureaux, Santo Domingo	July	26,	1899
King Humbert of Italy	July	29,	1900
President McKinley. Sept. 6; d.	Sept.	14,	1901
Alexander of Servia	June	11,	1903

Many attempts at assassination have been unsuccessful. Among those within the last century may be named: Against Alexander III. of Russia, repeatedly; Alfonso XII. of Spain, 1878 and 1879; Amadeus of Spain, 1872; Duc d'Aumale, 1841; Prince Bismarck, 1866 and 1874; Francis Joseph of Austria, 1853; George III. of England, 1786 and 1800; George IV. (when Regent), 1817; Humbert I. of Italy, 1878 and 1897; Isabella II. of Spain, 1847, 1852, and 1856; Louis Philippe, six attempts, from 1835 to 1846; Lord Lytton, viceroy of India, 1878; Napoleon I., by infernal machine, 1800; Napoleon III., twice in 1855, and Orsini's attempt in 1858; Queen Victoria, 10 June 1840, 30 May 1842, 3 July 1842, 19 May 1849, and 2 March 1882; William I. of Germany, 1861, 1875, and twice in 1878; President Diaz of Mexico and President Morales of Brazil, both in 1897; and the Prince of Wales in 1900.

Assas'sins, a term applied to a secret order of religious fanatics who flourished in the 11th and 12th centuries. They derived their name of assassins originally from their immoderate use of hasheesh, which produces an intense cerebral excitement, often amounting to fury. Their founder and lawgiver was Hassan-ben-Sabah, to whom the Orientals gave the name of Sheikh-el-Jobelz, but who was better known in Europe as the "Old Man of the Mountain." Their principal article of belief was that the Holy Ghost was embodied in their chief, and that his orders proceeded from the Deity. They believed assassination to be meritorious when sanctioned by his command, and courted danger and death in the execution of his orders. They were frequently styled Ismaili. A feeble residue of the sect, from whom proceeded the Druses, about A.D. 1020, has survived in Persia and Syria. The Syrian Ismaili dwell around Mesiode, and on Lebanon. They are under Turkish dominion, with a sheik of their own, and formerly enjoyed a productive and flourishing agriculture and commerce. Since the war with the Nassarians, 1809–10, they have dragged out a miserable existence, but are commended by modern travelers for their hospitality, frugality, gentleness, and piety.

Assault'. In law, an assault is a movement virtually implying a threat to strike, as when a person raises his hand or his cane in a menacing manner, or strikes at another but misses him. It is not needful to touch one to constitute an assault. When a blow actually takes effect, the crime is not simple assault, but assault and battery. Assault, however, is usually coupled with battery, and for the reason that they generally go together; but the assault is rather the initiation or offer to commit the act of which the battery is the consummation. An assault is included in every battery. An aggravated assault is one performed with the intention of committing some additional crime, such as an assault with intent to commit rape, assault with intent to murder, an assault with a deadly weapon, an indecent assault. The defenses usually interposed in cases of assault are self-defense, recapture of property, ejectment of trespassers, defense of property, defense of family, accident, etc. A person assaulting another may be prosecuted by him for the civil injury, and also be punished by the criminal law for the injury done to the public.

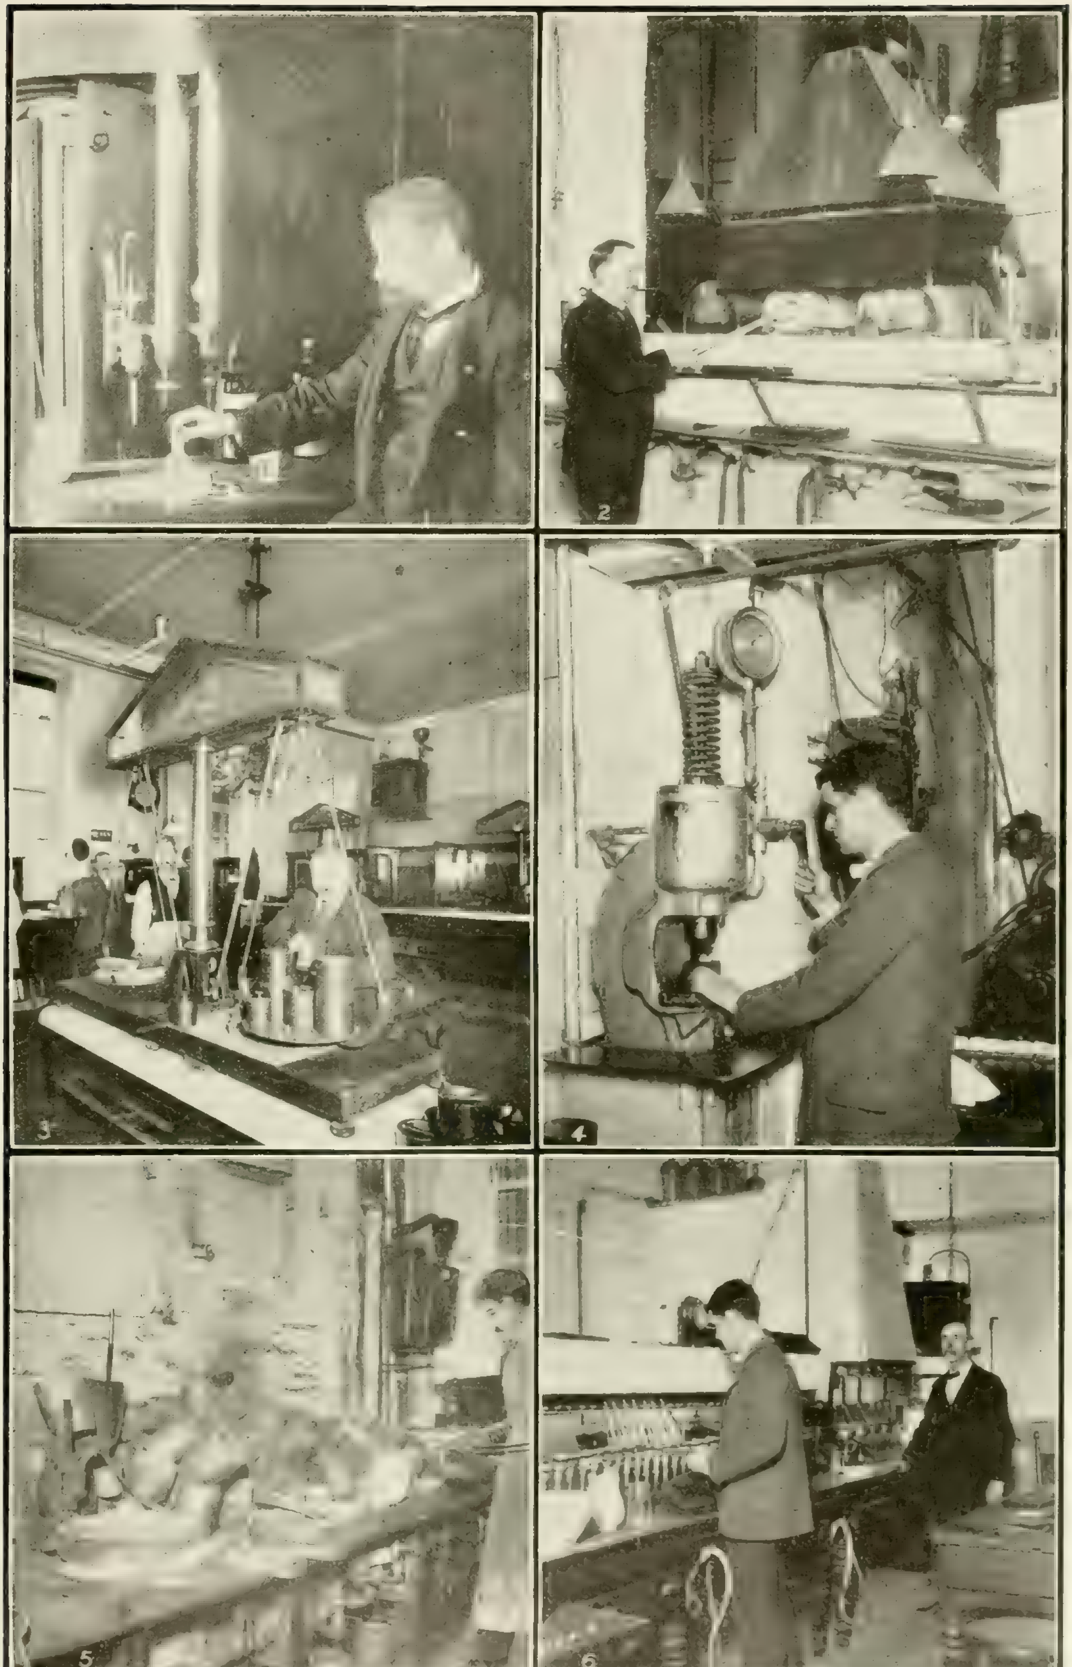
In military language an assault is a furious effort to carry a fortified post, camp, or fortress, where the assailants do not screen themselves by any works. It is the appropriate termination of a siege which has not led to the capitulation of the garrison. To give an assault: To attack any post. To repulse an assault: To cause the assailants to retreat; to beat them back. To carry by assault: To gain a post by storm. In fencing, an assault of arms is an attack on each other (not in earnest), made by two fencers to exhibit or increase their skill. (Sometimes it is used in a wider sense for other military exercises.)

Assaye, as-sī', a village in southern India, where Wellington gained a famous victory in 1803. With only 4,500 troops at his disposal he completely routed the Mahratta force of 50,000 men and 100 guns. The victory, however cost him the loss of more than a third of his men.

Assay'ing, the art of testing ores or alloys, for the purpose of determining the amount of some particular metal that is present in the material analyzed. Assays may be made by "wet" or "dry" methods, and will vary greatly in detail, according to the metal to be determined. The present article will be chiefly devoted to the usual process of estimating gold and silver in the "dry" way. The mode of procedure is substantially the same, whether the assay is made upon ore or upon bullion, except as to the method of obtaining the sample to be examined. If the material proposed for the assay is bullion, or any metallic alloy, the sample for examination is obtained by drilling into the specimen in different places, and mixing the borings. In the case of an ore, the usual method of obtaining a sample for assaying is by "quartering." If this is done by hand, every tenth shovelful of the ore to be examined is thrown upon the floor, until a conical heap containing perhaps ten tons has been accumulated. This heap is next flattened somewhat, and divided into four quarters, as nearly equal as possible. Two of the diagonally opposite quarters are thrown back into the main body of ore, and the remaining two quarters are thoroughly mixed, spread out into a second pile, and "quartered" again in the same manner. The process is continued (the ore being crushed in the meantime as often as appears necessary) until the original sample has been reduced to from one to three pounds, after which it is ground fine, and the specimens desired for examination are made up by random selections from the final pulverized product. More commonly, ores are sampled by mechanical or semi-mechanical methods, and the sampling is not done by the miner, but by a "campling mill," which acts as the agent both of the miner and of the smelting works. In such cases the ore is first shipped to the sampling mill, where it is unloaded, weighed, crushed, and passed through a chute, in which one quarter is mechanically selected and passed into a separate bin. The quarter thus mechanically reserved is next thoroughly mixed, after which the "cutting down" is commenced. This consists in removing the ore from the floor by means of a specially-constructed sampling shovel which catches about half of it, and lets the remainder fall into a barrow. The ore retained by the shovel is thrown into three buckets, in rotation, and the contents of the buckets are then coned up in one pile, and divided again in the same manner. The ore is then further crushed, and the process is continued until, finally, three samples, weighing about ten pounds each, are obtained. Part of each of these is sent separately to the assayer, who assays all three. If the results are not adjudged to be sufficiently accordant, the sampler concludes that the mixing was not well done, and the operations described are repeated. But if the three samples agree fairly well, their average is taken as representing the value of the ore; and on this basis the sampler settles with the miner, and afterward with the smelter, thus acting as a middle-man in the sale of the ore.

The specimen of ore received by the assayer is ground fine enough to pass through a 60-mesh or a 100-mesh screen, any "metallics" (or particles of metal that will not pass through the screen being carefully collected and reserved for a separate assay. If the ore is new to the assayer, his next step is to examine it microscopically, and to apply various preliminary tests, so that the general nature of the ore may be known before the quantitative work begins. If assays of the same material have been made before, and the only object is to ascertain the richness of this particular lot of ore, he may proceed directly to the process of "scorification," by which the gold and silver present in the ore are obtained in the form of a metallic button. The scorification process depends for its success upon the fact that when an ore of gold and silver is strongly heated with metallic lead in the presence of air, the baser metals that are present will oxidize, and the lead oxid that is also formed will dissolve the silica (or quartz) that is present; while the gold and silver will not oxidize, but will be left in the metallic state, alloyed with that portion of the lead which remains unoxidized. To apply this principle, 50 grains or so of the ore are mixed with some 500 grains of granulated lead, and placed in a sort of crucible, called a "scorifier." Another charge of 500 grains of lead is spread evenly over the mass, and a few grains of borax are sprinkled upon the top. The crucible and its contents are next heated for about three-quarters of an hour in a muffle to which a small amount of air is admitted, after which the melted mass in the crucible is poured into a mold to "set," or cool. When the mold is cold, it will be found to contain a button of metallic lead (in which the gold and silver originally in the ore are concentrated), and also a considerable amount of slag, consisting of oxid of lead, oxids of the base metals that are present in the ore, and silicates of lead, derived from the combination of the melted lead oxid with the quartz of the ore. The slag is readily detached from the metallic button by taps with a hammer.

The next step is to "cupel" the button, so as to obtain the gold and silver in a pure state. Cupellation is based upon the fact that when an alloy of gold, silver, lead, and base metals is heated in a current of air, the lead and the other base metals will oxidize, and the melted lead oxid ("litharge") will retain the other oxids in solution. Moreover, if the crucible in which the operation is carried out is porous, the melted lead oxid will soak into it, carrying the base oxids with it, and leaving a button of pure gold and silver behind.



[1] Humid Assay for Silver. [2] Muffle Furnaces for Fire Assay. [3] Weighing Room. [4] Pressing the Assay Sample [5] Melting Gold Bullion. [6] Extracting the Silver with Boiling Acid.

ASSAYING GOLD AND SILVER BULLION AT THE NEW YORK ASSAY OFFICE.

The "cupel" in which this is performed is made of bone-ash, and after the button left from the scorification process has been heated in the cupel for a short time, the process indicated above takes place, its completion being indicated, to the practised eye, by a play of iridescent colors on the cupelled button. The button is finally allowed to cool, and after it has been taken from the cupel, any small particles of bone-ash that remain adhering to it are removed by a brush.

If the original ore contained no silver, the assay is now completed, and it only remains to weigh the gold button, and compare its weight with that of the sample of ore used in the assay. But if silver is present, one other process, known as "parting," must be carried out, in order to separate the gold from the silver. Parting depends upon the fact that nitric acid will dissolve the silver out of an alloy of silver and gold, *provided* the weight of silver present is at least 2.5 times as great as the weight of the gold. In order to ensure the fulfillment of this necessary condition, the button, as it comes from the cupel, is melted with 2.5 or 3 times its own weight of silver that is known to be free from gold, and the alloy so formed is flattened out into a thin plate or ribbon, which is then rolled up into a little spiral, or "cornet," and boiled in nitric acid. The cornet is next washed in distilled water, and boiled again in nitric acid, to remove the last traces of silver; after which it is thrown into a crucible and melted into a button, for weighing. The button obtained by this final process consists of pure gold.

Assay Offices in the United States are government establishments in which citizens may deposit gold and silver bullion, receiving in return its value, less charges. The offices are in New York city; Boise City, Ida.; Helena, Mont.; Denver, Col.; Seattle, Wash.; San Francisco, Cal.; Charlotte, N. C.; and St. Louis, Mo.

The assay office in New York was established by law in 1853, and was opened in the autumn of 1854. The first assayer of the New York assay office was Dr. John Torrey of Columbia College, who was appointed in 1854 and held his position till 1873. On his death he was succeeded by his son, Herbert Gray Torrey, who has been in the office for 40 years. The superintendent of the assay office is Andrew Mason, who was appointed to his present position in 1883, having previously been assistant assayer and melter and refiner. While holding the latter office he substituted the use of sulphuric for nitric acid in the refining process, thus saving this one assay office $100,000 per annum.

The United States assay office is in a building located beside the more imposing subtreasury building, at the intersection of Wall and Broad streets, which marks one of the most historic spots in the country, namely, the site of the old Federal Hall, where Washington took the oath as first President of the United States. Although the building is small, yet it only masks a really large, inner building surrounded on all sides by office buildings and the sub-treasury. The assay offices, and particularly this one, have an important position in the world of finance, for here the precious metals — gold and silver — in all forms and conditions of fineness are assayed and refined. In brief, the work of this office consists in assaying or determining the value of gold and silver, in whatever form presented, as coin, jewelry, or in any other shape. Any one wishing to have gold or silver assayed in quantity or wishing to sell to the government, may present his property at the assay office, where he may have the metal reduced and made into bars, or if he prefers, he may sell his bullion to the government. The charge for doing the work is merely nominal, and based on the actual cost. Millions of dollars are stored at all times in the vaults. When the metal is received, the first step consists in weighing the coin, bars, jewelry, or tableware. This is done with great exactness and a receipt is given. Each person's holdings are placed in a box and are taken to the melting-room, where they are placed in crucibles with a flux and smelted and cast in ingot molds, the pouring being a highly picturesque operation. A small chip is taken from the bar for assay. See COINAGE.

If the depositor wishes to part with his bullion, the government pays for it at the prevailing price and proceeds to separate or part the gold from the silver. The price of gold never varies, costing $20.67 a fine ounce. Silver fluctuates with the market.

The importance of the assay office in its relation to the financial world, the treasury, and the mint cannot be overestimated. During the fiscal year ending 30 June 1900, the fineness of 11,802 melts of gold and silver deposits, 993 melts of fine gold and silver, also 1,050 melts of mixed metal, about 500 special deposits, 350 barrels of sweeps, 83,178 gold and silver bars were estimated, and about 60,000 cupels and the necessary "proof" gold and silver were made.

Assay Offices. See ASSAYING.

Assegai, ăs'se-gā, a short spear employed as a weapon among the Kaffirs of South Africa. It is made of hard wood tipped with iron, and used for throwing or thrusting.

Assemani, äs'se-mä'ne, (1) JOSEPH SIMON, a famous Orientalist: b. of a Maronite family in Tripoli, Syria, 1687; d. Rome, 14 Jan. 1768. He traveled on the Pope's commission through Egypt and Syria, collecting many Oriental manuscripts and coins for the Vatican library, of which he was appointed keeper. Of his numerous learned works, the most important is 'Bibliotheca Orientalis,' issued by order of Clement XI. and containing (in manuscript form) the Vatican codices in Syriac, Arabic, Persian, Turkish, Hebrew, Samaritan, Armenian, Ethiopian, Greek, Egyptian, Iberian, and Malabaric. (2) STEPHEN EPHODIUS (1707–82), also a learned author of books on Oriental learning. He was titular archbishop of Apomaca, Syria. Yet another nephew and Orientalist was (3) JOSEPH ALOYSIUS (1710–82), professor at Rome. (4) SIMON, a relative of the preceding, b. in Tripoli 1752; d. Padua 8 April 1821. He filled the chair of Oriental languages at Padua. He wrote an important work on ancient coins, 'Museo Cufico Naniano Illustrato' (1787–8).

Assemblages, General Theory of. The doctrine variously entitled *Mengenlehre* and *Mannigfaltigkeitslehre* by the Germans, *Théorie des ensembles* by the French, and sometimes referred to in English as the theory or doctrine of

manifolds or aggregates or by other analogous designations. Many of its ideas are at least as ancient as historical thought and have figured in important ways in logic, philosophy and mathematics steadily from the earliest times. On the other hand, many of the chief concepts involved in it, its characteristic notions, and their organization into a distinct and self-supporting body of coherent doctrine, may be said to constitute the latest great mathematical creation. Indeed the majority of the founders and builders of the doctrine, including Georg Cantor as easily the primate of them all, are still among the living. As mathematics is the most fundamental of the sciences, the theory of assemblages seems destined to be regarded, if it be not already regarded, as the most fundamental branch of mathematics. Viewed in retrospect, it appears as an inevitable product of the modern critical spirit. Already it is seen to underlie and interpenetrate both geometry and analysis. Its connection with mathematical logic is most intimate, often approximating identity with the latter; and even philosophy is surely, if but slowly, beginning to recognize in the theory of manifolds her own most inviting and promising field.

The Notions, Assemblage and Element.—Roughly speaking, any collection of objects or things of whatever kind or kinds is an assemblage. Each object in the collection is called an element of the assemblage. An assemblage, to be mathematically available, must be defined, or, as usage has it, well-defined (*wohldefinirt, bien defini*). An assemblage is defined when, by the logical principle of excluded middle, it can be regarded as intrinsically determined whether an arbitrarily given object is or is not an element of it. Means may or may not be known for making the determination actual or extrinsic. Thus if the elements of the assemblage be completely tabulated, the determination can be actually effected by comparing the given object with the elements of the table. Again, if an assemblage, such as that of the endless sequence 1, 2, 3, . . . of integers, be given by a definite law of formation of its elements, the law will generally enable one to determine actually whether any given object, as 5 or $\frac{1}{2}$ or an apple or a sunset, is an element of the assemblage or not. But the possession of such means is not essential to the notion of defined assemblage. A real * number is called *algebraic* or *transcendental* according as it is or is not a root of an equation of the form, $a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \ldots + a_{n-1}x + a_n = 0$, having integral coefficients. Any real number, no matter what its origin or definition, is either algebraic or transcendental; it cannot be both and it cannot be neither. Hence the real algebraic numbers constitute a defined assemblage, and so, too, the transcendentals. Nevertheless no means is known for ascertaining in every case whether a given number is algebraic or not. It was really a great achievement when the transcendental character of the long familiar classical numbers e and π was proved, for e by Hermite in 1874 and for π nine years later by Lindemann. Even the existence of non-algebraic numbers was unknown till it was proved by Liouville in 1851.

* The exigencies of the present undertaking demand the expository use of data drawn from the Theory of the Real Variable (which see) and other theories, although these are themselves branches of assemblage theory.

Depiction and Correspondence.—Assemblages will be denoted by large and elements by small letters. If, in any way, each element a of A is associated with an element b of B, A is said to be *depicted* on B. The b's so used are the *pictures* of the a's. If all the b's are thus made pictures, B is also depicted on A and the a's are pictures of the b's. If an a is a picture of a b and reciprocally, and if this relation holds for all the a's and b's, so that there is a one-to-one correspondence between them, the depiction is called *similar*. Obviously an assemblage can be depicted either similarly or dissimilarly on itself, generally in more than one way, often in an endless variety of ways.

The Concept Chain.—If the elements of A are elements of B, A is part of B. If in this case not all b's are a's, A is *proper* part of B. Any assemblage is part, but not proper part, of itself. One of the most important ideas connected with that of the depiction of an assemblage on itself is the notion of *chain*: if A be depicted on itself in any definite way, then any part of A that is thereby depicted on itself is a chain. In case of a given depiction of an A on itself, the most important of the chains so arising is that one that is composed of the elements, each taken but once, of all the chains having in common a previously chosen part of A. There is always one such special chain for a given part and given mode of depiction, but it changes with the part and with the mode independently. The theory of chains, due to Dedekind, has fundamental bearings in logic (see INDUCTION, MATHEMATICAL).

The Concept of Equivalence and Sameness of Power.—If A and B are such that each may be similarly depicted on the other, *i.e.*, if a one-to-one correspondence can be established between the elements of A and those of B, A and B are said to be *equivalent* or to have the *same power* (*Mächtigkeit*), a relation symbolically expressed by writing $A \backsim B$ or $B \backsim A$. Thus if A denote the assemblage of positive integers and B denote, say, the even positive integers, $A \backsim B$, for plainly one may pair 1 with 2, 2 with 4, 3 with 6, and so on. Other ways of pairing A and B in this case will readily occur to the reader.

Distinction of Finite and Infinite.—An assemblage is *finite* or *infinite* according as it has not or has the same power as some proper part of itself. Thus A of the last example is infinite. So, too, is B, for it is easily seen that if $A \backsim B$ and if either A or B is infinite, so is the other. Also, if $A \backsim B$ and if A or B is finite, so is the other. The foregoing definition of infinite is one of the most fruitful of modern concepts. It is due independently to Dedekind and Georg Cantor. Sometimes an infinite assemblage is defined to be one that cannot be exhausted or emptied by removing from it one element at a time. It has been proved that the two definitions are logically equivalent. But for the purposes of investigation, the former is found to be by far the better instrument. An infinite assemblage is often described as *transfinite*.

Denumerability.—Let A denote the assemblage of positive integers. Any assemblage B such that $B \backsim A$ is said to be *denumerable* or to have the power of the denumerable assemblage. As $A \backsim A$, A is itself denumerable, and it serves conveniently as the *type* of denumerable assem-

blages. The domain of such assemblages is exceedingly rich and is replete with surprises. For example, though the rational fractions, that is, fractions having integral terms, are so numerous that between any two of them, however near to each other in value, there is an infinity of others, nevertheless the assemblage of rational fractions including the integers is denumerable. Of this the reader can quickly convince himself by reflecting that there is but a finite number of such fractions of which each has a specified integer n for sum of its terms. Thus, if $n=2$, one has 1 or $\frac{1}{1}$; if $n=3$, one has $\frac{1}{2}$ and $\frac{2}{1}$; if $n=4$, $\frac{1}{3}$, $\frac{2}{2}$, $\frac{3}{1}$; and so on. Some are repeated; repetitions may be kept or rejected. Keeping them, the required equivalence is seen in the pairing: (1, 1); (2, $\frac{1}{2}$), (3, $\frac{2}{1}$); (4, $\frac{1}{3}$), (5, $\frac{2}{2}$), (6, $\frac{3}{1}$); . . . . In ordinary speech one is justified in saying that rational numbers are neither more nor less numerous than the integers or than the odd or the even integers. It is plain that the classic axiom, the whole is greater than any of its parts, is not valid for infinite assemblages. For finite assemblages it is valid absolutely, but for none other. For another example, consider the algebraic numbers, before mentioned. These include the rationals and infinitely many besides. Nevertheless the assemblage of all algebraic numbers is denumerable. The proof is too long to insert here. Yet more astonishing is the theorem that an assemblage composed of all the elements of a denumerable infinity of denumerably infinite assemblages is denumerable.

The Power of the Continuum.—At this stage the query is natural: is every possible assemblage denumerable? The answer is negative. The assemblage of all real numbers, *i.e.*, of all rationals and irrationals, is said to constitute a *continuum*. So, too, the assemblage of points of a straight line is a continuum, in particular a *linear* continuum. The last two assemblages are in fact of the same power, but neither is denumerable. This is demonstrated by letting $a_1, a_2, \ldots, a_n, \ldots$ represent *any* denumerable assemblage of real numbers and then proving that between any two arbitrarily assumed numbers α and β there is one number and therefore an infinity of numbers not in the given sequence. From this proposition of Cantor's the existence of transcendental numbers, which had been otherwise previously proved by Liouville, follows as a corollary. Any assemblage equivalent to that of the real numbers or to that of the points of a straight line is said to have the power of the continuum. The assemblage of points of any line-segment however short or, what is tantamount, the assemblage of numbers between any two numbers however nearly equal, has the power of the continuum. Indeed, either of these assemblages is a continuum. But an assemblage may have the power of the continuum without being a continuum. For example, the assemblage of transcendental numbers, though it is not a continuum, has the power of a continuum. In fact, the assemblage left on suppressing from a continuum any denumerable assemblage of elements is equivalent to the original assemblage. This last is a special case of the proposition: if A be infinite, and if the remainder R on suppressing a denumerable part of A be infinite, then $R \backsim A$. As above seen the power of the continuum is higher than that of the denumerable assemblage, but whether it is the *next* higher is an outstanding question. There are higher powers than that of any given power (unless this last be that of the assemblage of *all* things, a concept whose admissibility is questioned), but no assemblage of points has a power higher than that of a continuum. On the contrary, it is one of the most marvelous of known facts that the assemblage of points on a line-segment however short is equivalent to the assemblage of all the points of space, nay, is equivalent to all the points of a space having not merely, like our own, three dimensions, but a denumerable infinity of dimensions.

Limit-points, Dense and Derived Assemblages.—The *neighborhood* or vicinity of a point p is a region *small at will* taken about p. If p be in space, the neighborhood may be a sphere having p as center; if p be in a plane or in a line, the neighborhood will naturally be a circle or a line-segment. The following discussion, conducted for assemblages of points of a straight line, is readily extensible to other point assemblages. Denote by P any given assemblage of points of a line. If there be a point p, in P or not, such that in the neighborhood of p there is one point (and hence an infinity of points) of P, then p is a *limit-point* of P. If p be in P but not a limit-point, p is an *isolated* point of P. The assemblage of all the limit-points of P is the *first derived* assemblage $P^{(1)}$ of P. The first derived of $P^{(1)}$ is the *second* derived of P, namely, $P^{(2)}$; and so on. If P be finite, its $P^{(1)}$ contains no points, it is *empty*. If P be infinite and in a segment, $P^{(1)}$ contains at least one point—a proposition of exceeding importance in function theory. If the nth derivative $P^{(n)}$ be empty and the preceding derivative contains one or more points, P is said to be of *first genus* and nth *species*. If $P^{(n)}$ contain points for every positive integral value of n, P is said to be of *second* genus. Every point of a given derivative of P is a point of each preceding derivative, but P may contain points not in any of its derivatives. If some or all of the points of P are in an interval $(\alpha \ldots \beta)$ and if every sub-interval of the given one contains a point or points of P, P is said to be *dense throughout* the given interval. For example, the assemblage of points whose distances from a fixed point of the line are rational numbers is dense throughout every interval. If P be dense throughout a given interval, so is every derivative; in fact, each derivative in such case contains all points of the interval, and conversely. Hence one might *define*: P is dense throughout an interval when and only when $P^{(1)}$ contains every point of the interval. Obviously, if P is dense throughout an interval, P is of second genus, and so, too, are its derivatives. It follows that if P or one of its derivatives be of first genus, P is not dense in any interval. But it is not true that every P of second genus is dense throughout some interval.

Greatest Common Divisor, Least Common Multiple.—The equation $P \equiv Q$ will signify that the point assemblages P and Q are identical. Two assemblages having no element in common are said to be *without connection*. If P contains all and only the points of the assemblages P_1, P_2, . . . , every two of the latter being without connection, the fact is expressed by writing $P \equiv (P_1, P_2, \ldots)$. A part of P is called a *divisor* of it, and P is a *multiple* of each of its divisors.

The symbol, $D(P_1, P_2, \ldots)$, is read *greatest common divisor* of $P_1, P_2, \ldots$ and is the assemblage of their common points. $M(P_1, P_2, \ldots)$ is read *least common multiple* of $P_1, P_2, \ldots$ and is the assemblage of all the different points of the P's, it being understood that the latter have no common point. To express that P is empty, one may write $P \equiv 0$. If and only if P and Q are without connection, $D(P, Q) \equiv 0$. Each derivative of P is a divisor of every preceding derivative. If P is of second genus, then $P^{(1)} \equiv (Q, R)$, where Q is the assemblage of those points of $P^{(1)}$ that are not common to $P^{(1)}$, $P^{(2)}, \ldots$, and R is the assemblage of those that are common.

Transfinite Derivatives.—R is therefore defined by the equation $R \equiv D(P^{(1)}, P^{(2)}, \ldots)$ or by $R \equiv D(P^{(2)}, P^{(3)}, \ldots)$, or by $R \equiv D(P^{(n_1)}, P^{(n_2)}, \ldots)$, where $n_1, n_2, \ldots$ are a denumerably infinite assemblage of increasing positive integers. R is obviously a derivative of P, but the *order* of the derivative is not expressible by a number of the sequence 1, 2, 3, . . . ; these numbers are finite, the order of the derivative is transfinite, is denoted by ω, and one may write $R \equiv P^{(\omega)}$. The first derivative of $P^{(\omega)}$ is denoted by $P^{(\omega+1)}$, and the nth by $P^{(\omega+n)}$. If $P^{(\omega)}$ have a derivative of transfinite order ω, it is denoted by $P^{(2\omega)}$. Continuation of the process yields $P^{(\omega^2)}$, $P^{(\omega^\omega)} \equiv D(P^{(\omega)}, P^{(\omega^2)}, P^{(\omega^3)}, \ldots)$, $P^{\left(\omega^{\omega^\omega}\right)}$, and so on endlessly. For any assemblage P of first genus, $P^{(\omega)} \equiv 0$, an equation serving to characterize assemblages of first genus. Assemblages of second genus are definable for which the derivative of any given transfinite order shall consist of a single specified point.

If $D(P, P^{(1)}) \equiv 0$, P is an assemblage of *isolated* points. From any assemblage P, an assemblage Q of isolated points is obtainable by suppressing from P the assemblage $D(P, P^{(1)})$, and one may write $Q \equiv P - D(P, P^{(1)})$. It is known that if P be an assemblage of isolated points, it is denumerable, though, as above noted, the converse is not true. Also, if $P^{(1)}$ is denumerable, so is P; but not conversely, for, for example, the assemblage of rational fractions is denumerable, while its first derivative is a continuum, namely, the assemblage of real numbers. Again, if P be of second genus, and if $P^{(\alpha)}$, α being finite or transfinite, be denumerable, so, too, is P denumerable. A very remarkable theorem is the following: if P be in any given interval and if $P^{(1)}$ be denumerable, the points of P can be enclosed in a *finite* number of sub-intervals having a sum less than *any* prescribed length.

Perfect Assemblages.—If P and $P^{(1)}$ coincide, P is called a *perfect* assemblage; in the contrary case, imperfect. For example, if P is the assemblage of points of the interval from p_1 to p_2, including p_1 and p_2, P is perfect; but if P includes only the points *between* p_1 and p_2, P is imperfect, for clearly $P^{(1)}$ includes p_1 and p_2. The definition just given is Cantor's. Another current definition is that by Jordan: P is perfect if it *includes* $P^{(1)}$. It has been proposed to distinguish the two by describing an assemblage, if perfect in Cantor's sense, as *absolutely perfect*, and, if perfect in Jordan's but not in Cantor's sense, as *relatively perfect*. It has been proved that if P be relatively perfect, the assemblage R which results on suppressing $P^{(1)}$ from P is denumerable. But it is not true that every absolutely perfect assemblage is decomposable into a relatively perfect assemblage and a denumerable assemblage. The theory of perfect assemblages, though exceedingly subtle, is far simpler than that of imperfect assemblages. Every derivative of P is relatively perfect. There are absolutely perfect assemblages not dense in any interval.

Measure and Measurable Assemblages.—An assemblage P of all the points in a denumerable infinity of intervals that do not overlap and whose total length is s is said to have the *measure* s. If P and P' be without connection and have measures s and s', the measure of $M(P, P')$ is $s+s'$. If s and s' be the measures of P and P', and if P' be a divisor of P, the measure of $P-P'$ is $s-s'$. The measure of an assemblage is always *zero* or *positive*. The measure of any denumerable assemblage is zero, but zero may be the measure of a non-denumerable assemblage, and an assemblage is non-denumerable if its measure be not zero. An assemblage is said to be *measurable* only in case the foregoing definitions associate with it the notion of measure. A *restricted* or limited assemblage is one such that the distance between every pair of its points is less than a prescribed number. It has been proved that every restricted assemblage that is perfect relatively or absolutely is measurable. The doctrine of the measurability and content of assemblages is of great importance, but it cannot be further entered into here.

Improper Infinite and Proper Infinite, or Transfinite.—The *ordinary* notion of mathematical infinity is that of a finite variable, such as $\tan \alpha$, which can take a finite value greater than any previously specified finite value; and such an equation as $\tan 90° = \infty$ is understood by mathematicians to be a kind of short-hand for saying that, by taking α near enough to 90°, $\tan \alpha$ can be made to exceed any preassigned finite number, and it does not mean that ∞ is a value that $\tan \alpha$ may assume. Similar illustrations abound. Such a variable as thus remains always finite but may be made *large* at will is sometimes described as an *Infinite* (variable) in analogy with the reciprocal notion of *Infinitesimal*, a variable that remains always finite but may be made *small* at will. Such infinites are described by Cantor as *improper* infinites. On the other hand both geometry and analysis have long recognized another sort of infinite, *viz.*, one that is not variable but is *constant*. Such an infinite, for example, is the distance from any finite point of a range (see PROJECTIVE GEOMETRY) to the point common to the range and any parallel range. Another example is the distance from any finite point of the complex plane and the «infinite point» of the plane (see COMPLEX VARIABLE). Such infinites are styled by Cantor *proper infinites*, or transfinites. The examples just given of transfinites are transfinites *just* beyond the border of the finite. Cantor has generalized the generalization, and by one of the boldest procedures in the annals of mathetic genius he has created higher and higher classes of transfinite assemblages and numbers and subjected them to a logically consistent system of laws of operation. Of that procedure and of its results a brief account will now be given.

Principles of Number Generation, or of Definition of Classes.—These principles are three in

number: (1) *adding unity, or 1, to a number already formed;* (2) *in case of any given endless succession of integers having among them no greatest, positing a new integer that shall be the first greater than each integer of the succession;* (3) *the imposition on numbers generable by* (1) *and* (2) *of the condition that the succession of numbers preceding any given number so generated shall have the power of a class of numbers already defined.* The last is known as the principle of *arrest* or *limitation.* Cantor names the principles «the three logical moments», an ideally improper designation, for the applications of the principles are precisely the points in his procedure where it transcends logic and rises to the level of the creative or generalizing will. Generalization is neither logical nor illogical, it is always superlogical, an act of will directed by immediate perception.

The first class (I) of integers is the denumerably infinite assemblage of *finite* integers $1, 2, 3, \ldots \nu, \ldots$; generated or generable by (1). (I) contains no greatest and no last. By (2) the number ω is given to be the first integer greater than every number of (I). Combination of (1) and (2) yields $\omega+1$, $\omega+2, \ldots$, 2ω, $2\omega+1, \ldots$, $\nu_0\omega_\mu+\nu_1\omega_{\mu-1}+\ldots+\nu_{\mu-1}\omega+\nu_\mu$, $\ldots$, $\omega^\omega, \ldots$, $\omega^{\omega^\omega}, \ldots$, $\alpha, \ldots$, in endless succession. Herewith, however, is not *defined* a class of numbers that can be transcended by (1) and (2). The second class (II) of integers is defined by aid of (3) thus: it consists of those numbers that are generable by (1) and (2), that are orderable as in the preceding sequence, and that are such that all those which come before any specified one of them, say α, shall have the power of class (I). It has been proved that (II) has a power different from, indeed next higher than, that of (I). Combination of the three principles suffices to define distinct classes of higher and higher power, there being no restriction on the sublime crescendo except such as may inhere in the constitution of mind.

Transfinite Cardinal Numbers and their Laws.—The reader will naturally ask: Are the transfinite integers subject to law? They are, a fact best seen on approaching the matter from another but closely related point of view, as follows: Denote by A any assemblage of elements a; symbolically, $A=\{a\}$. On disregarding *both* the *character* of the a's and any and every *order* of their arrangement, a new assemblage, an *orderless* assemblage of *characterless* elements (*units*), arises, called the *power* or *cardinal number* of A and denoted by the symbol $\overline{\overline{A}}$. Herewith the term *power* (*Mächtigkeit*) is itself defined; *sameness of power* was defined above. Plainly every assemblage has a definite power, or cardinal number. Note that the cardinal number of an assemblage is by definition a definite assemblage: that which results on abstracting (the attention) from the *order* and *kind* of its elements. The equation $\overline{\overline{A}}=\overline{\overline{B}}$ means that A and B have the same or equal powers or cardinal numbers. It is easily seen that, when and only when $A \backsim B$, $\overline{\overline{A}}=\overline{\overline{B}}$. If $A, B, C, \ldots$ have no common element, the assemblage of all the elements involved will be denoted by $(A, B, C, \ldots)$. If also $A', B', C', \ldots$ have no common element, and if $A\backsim A'$, $B\backsim B'$, $C\backsim C', \ldots$, then $(A, B, C, \ldots)\backsim(A', B', C', \ldots)$, and the cardinal numbers of these composite assemblages are equal, or the same.

Notion of Greater and Less Powers or Cardinals.—If A and B are such that A has no part equivalent to B and that B has a part equivalent to A, the cardinal number of A is said to be *less* than that of B, that of B *greater* than that of A; symbolically, $\overline{\overline{A}}<\overline{\overline{B}}$, or $\overline{\overline{B}}>\overline{\overline{A}}$. If α, β, γ are cardinal numbers, and if $\alpha<\beta$, and $\beta<\gamma$, then $\alpha<\gamma$. Any one of the relations $\alpha=\beta$, $\alpha<\beta$, $\alpha>\beta$, excludes the other two. But it does not *follow* that every pair of cardinals α and β must satisfy one of the three relations, though they in fact do. This last proposition belongs to the theory of *well-ordered* assemblages, a term explained at a later stage of this writing.

Addition of Powers or Cardinals.—If α and β be the cardinal numbers of A and B, A and B having no common element, and if γ be the power of (A, B); then $\alpha+\beta=\gamma$. Such is the definition of addition. As a power is an orderless assemblage, $\alpha+\beta=\beta+\alpha$, and, in case of any three powers, $\alpha+(\beta+\gamma)=(\alpha+\beta)+\gamma$; that is, addition of powers is *commutative* and *associative.*

Multiplication.—Let $A=\{a\}$ and $B=\{b\}$. Associate each a with each b. Consider each pair (a, b) as an element. The assemblage of these is denoted by $(A\cdot B)$. Hence $(A\cdot B)=\{(a, b)\}$. The power γ of this last obviously depends only on the powers α and β of A and B. Hence the definition of *product*: $\alpha\cdot\beta=\gamma$. As the power, or cardinal number, of an assemblage is orderless, it is readily seen that $\alpha\cdot\beta=\beta\cdot\alpha$, and that, for any three powers, $\alpha\cdot(\beta\cdot\gamma)=(\alpha\cdot\beta)\cdot\gamma$, $\alpha\cdot(\beta+\gamma)=\alpha\cdot\beta+\alpha\cdot\gamma$; that is, multiplication of powers is *commutative*, *associative*, and *distributive.*

Involution.—If with each a of A a b of B be associated, any a and the associate b will be a *pair.* The same b may enter two or more pairs. The assemblage of all the pairs resulting from any such definite association is called a *covering* of A with B, and is denoted by $f(A)$. A different covering results if with any a there be associated a b not associated with it before. The assemblage of all possible coverings of A with B is denoted by $(B|A)$; then $(B|A)=\{f(A)\}$. The power γ of $(B|A)$ depends only on the powers α and β of A and B; hence the *definition*: $\alpha^\beta=\gamma$. It is readily seen that, if α, β, γ denote any three powers, $\alpha^\beta\cdot\alpha^\gamma=\alpha^{\beta+\gamma}$, $\alpha^\gamma\cdot\beta^\gamma=(\alpha\cdot\beta)^\gamma$, and $(\alpha^\beta)^\gamma=\alpha^{\beta\cdot\gamma}$.

It is an interesting fact that by means of the foregoing definitions of power, and addition, multiplication, and involution of powers, the definition and the fundamental properties of the ordinary (finite) cardinals $1, 2, 3, \ldots, \nu \ldots$ can be rigorously deduced.

The Smallest Transfinite Cardinal.—The cardinal number of the assemblage $\{\nu\}$ of finite cardinals is denoted by $\aleph_0$, alef-null. Symbolically, $\aleph_0=\overline{\overline{\{\nu\}}}$. The transfinite number $\aleph_0$ has the properties: $\aleph_0+1=\aleph_0$; $\aleph_0>\mu$, where μ is any finite cardinal; $\aleph_0<\alpha$, where α is any transfinite cardinal different from $\aleph_0$; $\aleph_0+\aleph_0=\aleph_0$; $\nu\cdot\aleph_0=\aleph_0\cdot\nu=\aleph_0$, where ν is any finite cardinal; $\aleph_0\cdot\aleph_0=\aleph_0$; $\aleph_0{}^\nu=\aleph_0$; etc. It is one of the wondrous facts met with in the doctrine of transfinite assemblages that the cardinal number of the points of space or other continuum is precisely $2^{\aleph_0}$.

Simply Ordered Assemblages, Order-types.—A is *simply ordered* when and only when its ele-

ments a are so disposed that of every pair a_1, a_2 of them, one, as a_1, precedes, *i.e.*, has *lower rank* and the other, as a_2, comes *after*, *i.e.*, has *higher rank*, and of every triplet a_1, a_2, a_3, a_1 is lower than a_3, if a_1 is lower than a_2 and a_2 is lower than a_3. To say symbolically that a_1 is lower in rank than a_2 and that a_2 is higher than a_1, we write either $a_1 \} a_2$ or $a_2 \} a_1$. A simply ordered assemblage that is further so arranged that it has an element of *lowest* rank, a *first* element, and that every part of it has a first element, is said to be *well-ordered.* For example, the assemblage of rational fraction greater than zero and less than one, if arranged in natural order, so that the larger the fraction the higher its rank, is simply ordered but not well-ordered. The same assemblage can, however, be well-ordered, thus: $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{1}{5}, \frac{1}{6}, \frac{2}{5}, \frac{3}{4}, \ldots$, where the scheme is that $\frac{p_1}{q_1}$ shall have lower rank than $\frac{p_2}{q_2}$ when p_1+q_1 is less than p_2+q_2, and if $p_1+q_1=p_2+q_2$, then the fraction having the smaller number for sum of its terms shall have the lower rank. It has been very recently proved that every assemblage can be well-ordered. Immediate important consequences are: (1) every transfinite assemblage can be so ordered that after each element there shall be a *next*; (2) every assemblage can be so arranged that every sequence $a_1, a_2, a_3, \ldots$ of its elements, for which $a_1 \} a_2$, $a_2 \} a_3, \ldots$, shall have an end; (3) every pair of assemblages are comparable in respect to their cardinal numbers.

If A be a simply ordered assemblage, the new assemblage obtained by abstracting from the character of the elements of A is called the *order-type* of A and is denoted by $\overline{A}$. Obviously, $\overline{A}$ is simply ordered. If A and B are simply ordered, and if their elements can be paired in one-to-one fashion so that the *rank* relation of every two elements a_1 and a_2 of A shall be the same as the rank relation of their correspondents b_1 and b_2 in B, then A and B are said to be *similar*, and to be *depictable* on one another. This definition of similar and depictable, it is noteworthy, are more restricted than that above given. The similarity of two similar simply ordered assemblages A and B is expressed by writing $A \simeq B$. If A is simply ordered, $A \simeq A$, and if B and C are simply ordered, and if $A \simeq C$ and $B \simeq C$, then $A \simeq B$. It is plain, too, that either of the relations, $\overline{A}=\overline{B}$, $A \simeq B$, implies the other.

To every order-type, or ordinal number, corresponds a power, or cardinal number. Thus to $\overline{A}$ corresponds $\overline{\overline{A}}$. The distinction of ordinal and cardinal is of no importance for finite assemblages, but is absolutely indispensable in the doctrine of transfinites. All order-types corresponding to a finite cardinal α are similar, but those corresponding to a transfinite cardinal present a countless variety and are said to constitute a *type-class* $[\alpha]$. To every transfinite cardinal corresponds such a type-class. Any type-class is itself an assemblage, namely, of order-types, and as such has its own cardinal number, which may be shown to be greater than that of each of the order-types involved.

Addition and Multiplication of Order-types.—If A and B are simply ordered, it will be understood that in their union (A, B) the elements of A have the same rank relation as in A, that the like is true of B, and that every a is of lower rank than every b. Hence (A, B) is simply ordered. If A' and B' are simply ordered and if $A \simeq A'$ and $B \simeq B'$, then $(A, B) \simeq (A', B')$. Hence the order-type of (A, B) depends only on $\alpha=\overline{A}$ and $\beta=\overline{B}$. Hence the definition of addition: $\alpha+\beta=\overline{(A, B)}$. Here α is the *augend* and β the *addend*. If α, β, γ be any three types, $\alpha+(\beta+\gamma)=(\alpha+\beta)+\gamma$; *i.e.*, addition of ordinals is associative; but, unlike cardinals, ordinals do not in general obey the *commutative* law. For example, if $\omega=\overline{E}$, where E denotes $e_1, e_2, \ldots, e_\nu, \ldots, e_\nu \} e_{\nu+1}$, and if f be any new element, then $1+\omega$ does not equal $\omega+1$, for (f, E) and (E, f) are not similar, the latter having a *last* element, while the former has not.

Next from the simply ordered assemblages A and B, form the assemblage S by replacing each b by an assemblage $A_b \simeq A$. It is easily seen that the order-type of S depends only on $\alpha=\overline{A}$ and $\beta=\overline{B}$. Hence the definition of multiplication: $\alpha \cdot \beta=\overline{S}$. Here α is multiplicand and β is multiplier. It is readily proved, in respect to three types α, β, γ, that $(\alpha \cdot \beta) \cdot \gamma=\alpha \cdot (\beta \cdot \gamma)$ and that $\alpha \cdot (\beta+\gamma)=\alpha \cdot \beta+\alpha \cdot \gamma$. That is, multiplication of ordinals like that of cardinals is *associative* and *distributive*. But in general ordinals do *not* obey, while cardinals always obey, the *commutative* law. The reader can easily convince himself that, for example, $\omega \cdot 2 \neq 2 \cdot \omega$.

Order-type of Rationals.—Denote by R the rational numbers greater than 1 and less than zero, taken in *natural* order. Let $\eta=\overline{R}$. Obviously η belongs to the type-class $[\aleph_0]$, for we have seen that R is denumerable. Moreover, R is *dense* and has no element of *lowest* rank and none of *highest*. By these three properties, R is completely characterized; that means that if A is simply ordered, dense, denumerable, and has neither lowest nor highest element, A and R are similar, and $\eta=\overline{A}$. It follows that $\eta+\eta=\eta$, $\eta \cdot \eta=\eta$, $(1+\eta)\eta=\eta$, $(\eta+1)\eta=\eta$, $(1+\eta+1)\eta=\eta$, but $\eta+1 \neq 1+\eta$, and, though $\eta+1+\eta=\eta$, $\eta+\nu+\eta \neq \eta$, if $\nu>1$.

Order-type of Linear Continuum.—Denote by θ the order-type of the linear continuum $X=\{x\}$, where $0 \leqq x \leqq 1$, and where X is disposed in natural order, *i.e.*, so that if x and x' be any two elements of X, $x \} x'$, when and only when $x<x'$. Now X is dense and perfect. It also contains R in such way that in respect to rank there are elements of R between every pair of x's. So is suggested the following fundamental theorem, which serves to characterize the type of the linear continuum completely: *If a simply ordered assemblage A is perfect and if it contains a denumerable assemblage P such that in respect to rank P has elements between every two elements of A, then $\theta=\overline{A}$.*

For detailed elaboration of the foregoing notions and for extensions of the doctrine, the reader is referred to the

Assem'bly, Constituent. See Assembly, National.

Assem'bly of Divines, a celebrated assembly appointed by the Long Parliament, and held at Westminster to determine upon the doctrine and liturgy of the English Church. By an ordinance passed 12 June 1643, 121 clergymen, with 10 Lords and 20 Commoners as lay assessors, were nominated as constituents of the assembly. The assembly began its sittings in July 1643, in Westminster Abbey, but in the meantime a royal proclamation had been issued forbidding the assembly to meet, which had the effect of inducing the greater part of the Episcopal members to absent themselves. The majority of those who remained were Presbyterians, but there was a strong minority of independents. A deputation was now sent along with commissioners from the English Parliament to the General Assembly of the Scottish Church and the Scottish Convention of Estates, soliciting their co-operation in the proceedings of the Westminster Assembly, and in September four Scottish clergymen, with two laymen, were admitted to seats and votes. The assembly continued to hold its sittings till February 1649. Among the results of its deliberations were the Directory of Public Worship, the Confession of Faith, and the Larger and Shorter Catechisms, which remain practically the standards of the Presbyterians to the present day. At the Restoration the whole proceedings of the Westminster Assembly were annulled as invalid. See Hethorington, 'History of the Westminster Assembly' (1843); Masson, 'Life of Milton' (1858–79).

Assem'bly, General, the name applied to the highest ecclesiastical court of the Established Church of Scotland. It consists of delegates from every presbytery, university, and royal burgh in Scotland, holds meetings annually, in the month of May, and usually continues to sit for 12 days. In its judicial capacity and as the court of last resort, the General Assembly has a right to determine finally every question brought from the inferior courts, by reference, complaint, or appeal. The laws enacted by the assembly, after receiving the sanction of a majority of presbyteries, are the established and permanent statutes of the Church, by which everything belonging to the ecclesiastical state, or to the Church courts, is authoritatively regulated. The United Free Church of Scotland has a General Assembly similar in its constitution and functions to that of the Established Church, and the same is true of the Presbyterian churches (q.v.) of Ireland and America.

Assem'bly, National, a body established in France in 1789. Upon the convocation of the states-general by Louis XVI., the privileged nobles and clergy refused to deliberate in the same chamber with the commons, or *tiers-état* (third estate). The latter, therefore, on the proposition of the Abbé Siéyès, constituted themselves an *Assemblé Nationale,* with legislative powers, 17 June 1789. They bound themselves by oath not to separate until they had furnished France with a constitution, and the court was compelled to give its assent. In the 3,250 decrees passed by the assembly were laid the foundations of a new epoch, and having accomplished this task, it dissolved itself 30 Sept. 1791. The term is also applied to a joint meeting of the Senate and Corps Legislatif, for the purpose of electing a chief magistrate or the transaction of other extraordinary business. See Stephens, 'History of the French Revolution' (1886–91); Doniol, 'La Révolution et la Féodalité' (1874).

As'sen, ä'sĕn, the capital of the province of Drenthe, Holland. Near it are the Giants' Caves, to which Tacitus makes allusion. Pop. 11,191.

Assent', in law, an undertaking to do something in compliance with a request. Approval of something done. Express assent is that which is openly declared. Implied assent is that which is presumed by law. Assent must be to the same thing in the same sense. It must embrace the whole of the proposition, must be exactly equal to its extent and provisions, and must not qualify them by any new matter. Unless express dissent is shown, acceptance of what it is for a person's benefit to take, is presumed, as in the case of a conveyance of land

The Royal Assent is the approbation given by the sovereign in Parliament to a bill which has passed both houses, after which it becomes a law. It may be given in person, when the sovereign comes to the House of Peers and the assent (in Norman French) is declared by the clerk of Parliament; or may be declared by letters-patent under the great seal, signed by the sovereign.

Assess'ment is the determining of the value of a man's property or occupation for the purpose of levying a tax. Determining the share of a tax to be paid by each individual. Laying a tax. Adjusting the shares of a contribution by several toward a common beneficial object according to the benefit received. Assessment of damages includes fixing the amount of damages to which the prevailing party in a suit is entitled. It may be done by the court through its proper officer, the clerk or prothonotary, where the assessment is a mere matter of calculation, but must be done by a jury in other cases. Insurance assessment is an apportionment made in general average upon the various articles and interests at risk, according to their value at the time and place of being in safety for contribution for damage and sacrifices purposely made, and expenses incurred for escape from impending common peril. An assessment is also made upon premium-notes given by the members of mutual fire insurance companies, constituting their capital, and being a substitute for the investment of the paid-up stock of a stock company, the liability to such

assessments being regulated by the charter and by-laws, 12 N. Y. 477; 14 Bart. N. Y. 374.

Asseteague (ăs'sẹ-tēg') **Island,** a small island off the coast of Virginia in Northampton County. Upon it is a lighthouse 150 feet in height.

Assiento, asyän'tō (Spanish, *asiento,* seat, contract, treaty), a term especially applied to an agreement between the Spanish government and a foreign nation to import negro slaves from Africa into the Spanish colonies in America, for a limited time, on payment of certain duties. The English were the sole possessors of this assiento till 1701. In 1713 the celebrated assiento treaty with Britain for 30 years was concluded at Utrecht. By this contract the English, among other privileges, obtained the right of sending a *permission* or *assiento ship,* so called, of 500 tons every year, with all sorts of merchandise, to the Spanish colonies. By the treaty of Madrid, 5 Oct. 1750, the contract was annulled.

As'signa'tion. See ASSIGNMENT.

Assignats, ạ-sẹ-nyạ, or ăs-ĭg-năts, a term applied to the paper money issued during the French Revolution. The French National Assembly after appropriating to national purposes the land belonging to the Church, instead of selling it at a time when its value was greatly depreciated, because of the unsettled state of affairs, issued bonds on the security of it, which were called assignats, as representing land *assigned* to the holder. This paper currency consisted chiefly of notes for one hundred francs each, though many of them were for lower sums. The first issue in 1790 amounted to 400,000,000 francs. The government was relieved by this plan, for the time being the assignats saved the Revolution. This arrangement for relieving the necessities of the government seemed so easy that recourse was repeatedly had to it, as the property of wealthy emigrés, until the amount arose to the vast sum of 46,000,000,000 francs, besides many forged notes. The consequence was that the value of assignats sank to almost nothing. In March 1796, a louis d'or (24 francs) bought 7,200 francs in assignats. They were withdrawn from the currency after this, and redeemed at a thirtieth of their nominal value, by "territorial mandates," a new kind of paper currency, which empowered the holder at once to take possession of public lands at the estimated value, while assignats could only be offered at a sale. These territorial mandates afterward became almost worthless and were returned to the government in payment of taxes or of land. Early in 1797 the system came suddenly to an end.

Assign'ment, a term denoting a transfer by deed of any property, or right, title, or interest in property, real or personal. Assignments are usually given for leases, mortgages, and funded property. In the United States, assignment is of broader signification and applies also to the transfer of real property by certain conveyance. In general, every right of property, real or personal, and every demand connected with a right of property, real or personal; and all choses in action, as bonds, notes, judgments, mortgages, debts, contracts, agreements, relating both to real and personal property, are assignable, and the assignment thereof will pass to the assignee a right of action in the name of such assignee against all parties liable to an action. Assignment carries with it all collateral securities held by the assignor for the collection of a debt or the fulfillment of a contract, and is subject to all the equities and charges which attached in the hands of the assignor. A personal trust, as the right of a master in his indentured apprentice, or the duties of a testamentary guardian, or the office of executor, trustee, etc., is not assignable. The validity of an assignment must be determined by the law of the State in which it was made, provided the thing assigned is subject of municipal or State law; but copyrights, patents, and government claims are governed by acts of Congress. In general, assignments should be recorded in the office prescribed by law, or are void as against those claiming under subsequent assignments. See BANKRUPTCY LAWS.

Assimilation, a term denoting the transformation of foods into living substance. The animal body is constantly changing. New compounds are being made from others; old products are cast off. There is a constant interchange of materials, some building up, others breaking down. The chief factors in the assimilative process are the foods and the oxygen in the air. For a discussion of the former, see DIGESTION; NUTRITION; for the latter, see RESPIRATION. See also METABOLISM.

Assiniboia, ăs-sĭn'ĭ-boi'ạ, a district in northwestern Canada, west of Manitoba, having the district of Saskatchewan on the north and Alberta on the west, and contains an area of 34,000,000 acres. It has a length of about 450 miles east and west by 205 miles north and south. Eastern Assiniboia, for a distance of some 120 miles west from its eastern boundary, is practically a continuation of the grain-growing area of Manitoba, and the soil is productive, producing excellent crops of wheat, coarse grain and vegetables. The main line of the Canadian Pacific Railway (q.v.) extends east to west almost through the centre of Assiniboia, and branch lines extend from Moose Jaw to the southeast corner of the district, and from Regina to the north through the central portion. The Manitoba and Northwestern Railway extends into the northwestern portion of the district from Manitoba, giving good facilities in the way of transportation. Other branches are being projected into southern Assiniboia. The district is well watered by the South Saskatchewan, the Qu'Appelle, Assiniboine, and other rivers, and the valleys along the rivers and creeks are very fertile and generally adapted to mixed farming. Similar conditions prevail in western Assiniboia. A marked development is taking place along the "Soo" line, and the land, which is very fertile, has been largely taken up by settlers from the United States. The principal towns are Regina, the capital, Halbrite, Weyburn, Yellow Grass, Milestone, Rouleau, Moosomin, Grenfell, Wolseley, Indian Head, Qu'Appelle, Saltcoats, Yorkton, and Medicine Hat. Pop. (1904) about 70,000. On 1 Sept. 1905 Assiniboia was united with the province of Saskatchewan and the eastern portion of Athabasca to form the new province of Saskatchewan.

Assin'iboine, a river of Canada, which flows through Manitoba and joins the Red River at Winnipeg, about 40 miles above the entrance of the latter into Lake Winnipeg. It has a somewhat circuitous course of about 500 miles and steamers ply on it for over 300 miles.

Assisi, as-sē'sē, a hill town in Italy, in the province of Umbria, 20 miles from Spoleto. It is the see of a bishop and is famous as the birthplace of Saint Francis, founder of the Franciscan Order, and of Saint Clara, foundress of a religious community for women. The splendid church built over the chapel where Saint Francis received his first impulse to devotion is one of the finest remains of the architecture of the Middle Ages. Pop. (1901) 17,378. See «Assisi» in 'Mediæval Towns Series' (1901).

Assize' of Jerusalem, a code of laws in force in the Christian kingdom of Jerusalem and Cyprus. It consisted of two parts, the assize of the high court with jurisdiction over the nobles, and the assize of the court of burgesses, or code of the common people. It was supposed for some time that the laws were framed by Godfrey de Bouillon; but this is now known to be incorrect. The assize of the high court was first framed as a code about 1255, the assize of the court of Burgesses, in the latter part of the 12th century, but the exact date is uncertain.

Assiz'es, an English legal term signifying the sessions of the courts held at intervals in every country by the judges. The whole country is divided into circuits, and three times in the year two judges, who are members of the highest courts in England, hold assizes in all the counties of their respective circuit. In London and Middlesex, instead of circuits, what are known as courts of *nisi prius* are held. At the assizes all the justices of the peace of the county are bound to attend, or else are liable to a fine; and also all the persons who have been summoned as grand jurymen or petit jurymen by the sheriff. At these assizes the judges sit under five separate commissions, some of which relate to civil and some to criminal causes or business. In this manner, and by these means, the jails are in general cleared, and offenders tried and convicted or acquitted at least every half year. In America there are no courts or sessions of courts technically called assizes. The judges, however, perform the same duties in the counties, within their respective circuits and jurisdictions, as the English judges, and generally in the same manner, that is to say, according to the course of the common law. Since 1808 there have been assize courts in the judicial system in France. With the English institutions, however, they have scarcely anything in common but the name. In the law of Scotland assize is the technical term applied in cases tried in the court of justiciary to the jury of 15 sworn men, selected by ballot from a greater number not exceeding 45.

Association Areas. In the brain of many lower animals as well as in that of man there are definite areas associated with other areas by sets of fibres, known as association fibres. These different areas act together in performing many of the complicated acts of human life. Thus, the general sensory area in the brain, that feels the skin sensations and determines their character, is in close association with the motor area determining the movements of the body in correspondence with the knowledge given by the sensory areas. Under the heading APHASIA several of these association areas are discussed. The studies of psychology and of mental diseases are largely concerned with the relations and connections of the association areas in the brain.

Bibliography.— Flechsig, 'Die Gehirn und Seele' (1896); Barker, 'Journal of Nervous and Mental Disease,' 1897, pp. 326–356.

Association Fibres, a term applied to those fibres that connect different parts of the brain, particularly those that unite different areas in the same hemisphere, distinguishing them from the commissural fibres that connect areas in different hemispheres, or projection fibres that bind the cerebrum with the lower cerebellar or spinal systems. These association fibres form late in childhood and on their development depends much of the increased intellectual growth of the individual.

Association of Ideas, a phrase current in philosophy and psychology since the days of John Locke. The term «association» has had, in this connection, many different meanings. In popular psychology, it indicates the way the mind passes from idea to idea; or the way one idea suggests or «reproduces» another. Thus, in passing from the thought of gold to the recollection of a recent visit to a mining camp and then to the plot of a novel laid in a mountainous region, one may be said to «associate» the story with the idea of the mining camp, and this, in turn, with the idea of gold. (See MEMORY.) It is but a step from this popular conception of association — association as «reproduction»— to the notion that association is an explanation of reproduction. Association then becomes (to change the figure) not the actual passage from idea to idea, but the intangible bond which holds ideas together and which enables one idea (that is, the «gold» idea) to drag after it another (the «camp» idea). This second interpretation of the term is in disrepute among psychologists because no evidence of such a bond as the interpretation implies is to be found in consciousness. It may be urged, however, that even if association in this causal sense be undiscoverable by introspection it may, nevertheless, be regarded as a general principle of mental activity; — as the means by which the mind creates knowledge. When, however, association is thus interpreted to mean a principle underlying and conditioning the process of knowing it passes from psychology to epistemology. (See PSYCHOLOGY.) The doctrine of Associationism, which is connected with the names of David Hume, James Mill, Alexander Bain and other «associationists,» rests upon this epistemological meaning of the term.

Returning to the psychological use of the word «association,» we may note that the popular conception stands in need of modification and precision. (1) To say that mind «associates» idea with idea implies that ideas are by nature

separate and distinct and require some "gentle force" (as Hume puts it) to bring them together. This is not true. Ideas are interwoven; they are organically connected; they are not held together as in a bundle. (2) In the second place, the popular use of the term is too narrow; a chain of actions, or of emotions, or of feelings, may be associated as well as a chain of ideas. In habitual performances, for example,— such as dressing — one act calls forth the next, this in turn the next, and so on; or emotion may be linked with emotion, as anger following fear; or, finally, associations may set out from a perception, as the thought of home from the sight of a letter. (3) Again, association does not necessarily imply a sequence of associated elements. It may be simultaneous, as well as successive; for example, I see the table before me and, at the same time, I apprehend it as a hard resisting substance, or I hear the rumble of a carriage behind me and I see, in my "mind's eye," its form and color. (See PERCEPTION.) (4) Finally, association in the popular sense simply states that idea follows idea; it tells us nothing of the nature of the associated consciousness; of how, that is, an association differs from a perception. Now association, in its strict technical sense, means the associated elements of consciousness; to illustrate, it means the mass of constantly shifting processes which make up mind while one is thinking gold — mining-camp — novel. Just as there exist typical groups of mental processes which underlie the perception of a landscape, a swinging pendulum or a musical composition, there exist other typical groups — such as those already mentioned — which are known as associations.

Psychological work upon association has been directed, for the most part, upon the conditions under which associative groups arise. These conditions have, since the days of Aristotle, been set down under the heading of "principles" or "laws" of association. Thus *a* is said to call up or reproduce *b* when *a* and *b* have, at some previous time, stood together in consciousness (law of contiguity), or when *a* has been the cause of *b* (law of causality), or when *a* resembles *b* (law of similarity), etc. At the present time, these "laws" of association are usually reduced to two; the law of contiguity and the law of similarity. But even these are by no means final or adequate statements of the conditions under which associations arise; for — to point to only two or three of their imperfections —"similarity" is an extremely ambiguous term; it may mean simple likeness, or partial identity, or likeness of relationship; and "contiguity" is indefinite — it does not determine how near processes must lie in consciousness in order for one to reproduce the other. Moreover, it should be said that there are thousands of contiguity and similarity connections that are never realized in association; this follows from the fact that almost everything is, to some extent, similar to everything else, and that the elementary processes of mind have appeared "contiguously" in almost every conceivable form of combination. Both terms are, then, too broad to have much significance. If we set them down as "laws," we have still to determine under what particular conditions a given association is formed. Many of these particular and more important conditions have been determined; they include recency, frequency, vividness (the more recently or frequently or vividly a process or group of processes has stood in consciousness the greater the liability of its appearing in an associative connection), the general interests of the individual mind (for example, botanical ideas crop up in the botanist's mind, geological ideas in the mind of the geologist), the presence or absence of inhibitory associations (if *a* has already stood associated with *b* and *c*, its chances for associating with *d* will be lessened), mood (unpleasant subjects crowd into mind when one is depressed), etc. The actual liability of a given association being formed is thus seen to rest upon a great number of possible conditions. So far as there is any truth in a general all-inclusive "law" of association it is best expressed as a law of neural habit. This law is formulated by W. James as follows: "when two elementary brain-processes have been active together or in immediate succession, one of them, on reoccurring, tends to propagate its excitement into the other." The relation of this law to the law of contiguity is obvious.

I. M. BENTLEY,
Assistant Professor of Psychology, Cornell University.

Associa'tion for the Protection of the Adirondacks, a society organized in 1902 and incorporated the same year for the purpose of preserving the forests, waters, game, and fish, and to maintain healthful conditions in the Adirondack region.

Assollant, as'sō'län', **Alfred,** a French novelist and political writer; b. Aubusson, 20 March 1827; d. Paris, March 1880. Having traveled extensively over the United States, he published, on his return, 'Scenes from Life in the United States' (1858), a series of tales which attracted a good deal of attention. Among his numerous novels are 'Two Friends in 1792' (1859), a story of the Reign of Terror; 'Brancas' (1859), a picture of the corruption under Louis Philippe; 'Gabrielle de Chênevert' (1865), portraying the provincial nobility before the Revolution; 'Pendragon' (1881), and 'Plantagenet' (1885).

Assommoir, L', la'sō'mwär', a novel by Emile Zola, entitled 'Gervaise' in the English translation, published in 1877. It forms one of the series dealing with the fortunes of the Rougon-Macquart family, and is a series of repulsive pictures unrelieved by one gleam of a nobler humanity, but only "realistic" as scraps: the life as a possible whole is as purely imaginative as if it were lovely instead of loathsome.

As'sonance, in poetry, a term used when the lines end with the same vowel-sound, but make no proper rhyme. Such verses having what we should consider false rhymes are regularly employed in Spanish poetry; as in *ligera, cubierta, tierra, mesa.*

Assos, ăs'ŏs, an ancient Hellenic port on the Gulf of Edremid, from whose still imposing remains the successful excavations, in 1881–3, of the American Institute of Archæology have brought to light the agora, with senate house and colonnade, a bath, theatre, gymnasium, statues of heroes, and seven Christian churches.

Assouan, a-swän', or **Assuan**, also called Eswan (Arabic *al suaan*, "the opening," that is, of the Nile; the ancient Syene, whence the red granite of the vicinity — from whose famous quarries were cut under the earliest dynasties so many of the huge obelisks and colossal statues that adorned the temples and palaces of Egypt — is called syenite), the southernmost city of Egypt proper, near Nubia, on the right or eastern bank of the Nile, and beside the first or lowest cataract. Near it are the islands of Philæ and Elephantine, the ruined monuments of the former of which are of such fascination to tourists; on the left bank are many rock tombs of the ancient dynasties. It is a garrison town, the central depot for the Sudan caravan trade, and the terminus of a railway to Alexandria which enhances its prosperity. Of still greater importance is the new dam which will add several hundred square miles outright to the arable soil of Egypt, besides steadying the fertility of the older lands, and which is described *in extenso* below. Pop. about 10,000, including the suburbs.

The monumental dam at Assouan, by far the greatest achievement of the kind in ancient or modern times, forms a reservoir in the Nile valley capable of storing 1,000,000,000 tons of water. It will not only produce a revolution in the primitive and laborious methods of irrigation in Egypt, but will reclaim vast areas of land that have hitherto been accounted as arid and worthless. The old system of irrigation was little more than a high Nile flooding of different areas of land or basins surrounded by embankments. Less than a hundred years ago, the introduction of perennial irrigation was first attempted by cutting deep canals to convey the water to the lands when the Nile was at its low summer level. When the Nile rose, these canals had to be blocked by temporary earthen dams, or the current would have wrought destruction. As a result, they silted up, and had to be cleared of many millions of tons of mud each year by enforced labor, much misery and extortion resulting therefrom. About half a century ago the first serious attempt to improve matters was made by the construction of the celebrated Barrage at the apex of the delta. This work consists, in effect, of two brick-arched viaducts crossing the Rosetta and Damietta, branches of the Nile, having together 132 arches of 16 feet 4 inches span, which were entirely closed by iron sluices during the summer months, thus heading up the water some 15 feet and throwing it at a high level into the six main irrigation canals below Cairo. In the summer months the whole flow of the Nile is arrested and thrown into the aforesaid canals. The old Barrage was constructed under great difficulties by French engineers, subject to the passing whims of their Oriental chiefs. About 15 years elapsed between the commencement of the work and the closing of all the sluices, and another 20 years before the structure was sufficiently strengthened by British engineers to fulfil the duties for which it was originally designed. Forced labor was largely employed in its construction, and at one time 12,000 soldiers, 3,000 marines, 2,000 laborers, and 1,000 masons were at work at the old Barrage.

In connection with the Nile reservoir, subsidiary weirs were constructed below the old Barrage to reduce the stress on that structure. The system adopted was a novel one, devised by Major Brown, inspector-general of irrigation in lower Egypt. His aim was to dispense almost entirely with plant and skilled labor; and so, without attempting to dry the bed of the river, he made solid masonry blocks under water by grouting rubble dropped by natives into a movable timber caisson. Both branches of the Nile were thus dammed in three seasons, at a cost, including navigation locks, of about $2,500,000. Many other subsidiary works have been and will be constructed, including regulators, such as that on the Bahr Yusuf canal. The most important of the works is the Barrage across the Nile at Assiout, about 250 miles above Cairo, which was commenced by Sir John Aird & Co. in the winter of 1898 and completed in 1902. The great dam at Assouan, 850 miles above Cairo, is not a solid wall, but is pierced with sluice openings of sufficient area for the flood discharge of the river, which may amount to 15,000 tons of water per second. There are 180 such openings, mostly 23 feet high by 6 feet 6 inches wide; and where subject to heavy pressure when being moved they are of the well-known Stoney roller pattern. The total length of the dam is about 1¼ miles; the maximum height from foundation, about 130 feet; the difference of level water above and below, 67 feet; and the total weight of masonry over 1,000,000 tons. Navigation is provided for by a "ladder" of four locks, each 260 feet long by 32 feet wide. As was the case at Assiout, the difficulties in dam construction are not in design, but in the carrying out of the works. When the "rotten rock" in the bed was discovered, Sir Benjamin Baker reported to Lord Cromer frankly that he could not say what the extra cost or time involved by this and other unforeseen conditions would be, and that all that could be said was that, however bad the conditions, the job could be done. Lord Cromer replied that the dam had to be completed whatever the time and cost involved. The contract was let to Sir John Aird & Co., of London, with Messrs. Ransomes and Rapier, of London, as sub-contractors for the steel work, in February 1898. Two months after signing the contract the permanent works were commenced, and before the end of the year thousands of native laborers and hundreds of Italian granite masons were hard at work. On 12 Feb. 1899, the foundation stone of the dam was laid by the Duke of Connaught. Many plans were considered by the engineers and contractors for putting in the foundations of the dam across the roaring cataract channels, and it was finally decided to form temporary rubble dams across three of the channels below the site of the great dam, so as to break the force of the torrent and get a pond of comparatively still water up stream to work in. Stones of from 1 ton to 12 tons in weight were tipped into the cataract, till finally a rubble mound appeared above the surface. The first channel was successfully closed on 17 May 1899, the depth being about 30 feet and the velocity of current nearly 15 miles an hour. In the case of another channel the closing had to be helped by tipping in railway cars themselves, loaded with heavy stones and bound together with wire ropes, making a mass of about 50 tons, the great mass being necessary to resist displacement by the torrent.

These rubble dams were well tested when the high Nile ran over them; and on work being resumed in November, after the fall of the river, water-tight sandbag dams, or "sudds," were made around the site of the dam foundation in the still waters above the rubble dams, and pumps were fixed to lay dry the bed of the river. This was the most exciting time in this stage of the operations, for no one could predict whether it would be possible to dry the bed, or whether the water would not pour through the fissured rock in overwhelming volume. Twenty-four 12-inch centrifugal pumps were provided to deal, if necessary, with one small channel; but happily the sandbags and gravel and sand embankments stanched the fissures in the rock and interstices between the great boulders covering the bottom of this channel, and a couple of 12-inch pumps sufficed. The masonry of the dam is of local granite, set in British Portland cement mortar. The interior is of rubble set by hand, with about 40 per cent of the bulk in cement mortar, four of sand to one of cement. All the face work is of coursed rock-faced ashlar, except the sluice linings, which are finely dressed. This was steam crane and Italian masons' work. There was a great pressure at times to get a section completed before the inevitable rise of the Nile, and as much as 3,600 tons of masonry was executed per day, chiefly at one point in the dam. A triple line of railway and numerous cars and locomotives were provided to convey the materials from quarries and stores to every part of the work. The maximum number of men employed was 11,000, of whom 1,000 were European masons and other skilled men. Mr. Wilfred Stokes, chief engineer and managing director of Messrs. Ransomes and Rapier, was responsible for the detailed designing and manufacture of the sluices and lock gates; 140 of the sluices are 23 feet high by 6 feet 6 inches wide, and 40 of them half that height; 130 of the sluices are on the "Stoney" principle with rollers, and the remainder move on sliding surfaces. The larger of the Stoney sluices weigh 14 tons, and are capable of being moved by hand under a head of water producing a pressure of 450 tons against the sluice. There are five lock gates, 32 feet wide, and varying in height up to 60 feet. They are of an entirely different type from ordinary folding lock gates, being hung from the top on rollers, and moving like a sliding coach-house door. This arrangement was adopted for safety, as 1,000,000,000 tons of water are stored up above the lock gates, and each of the two upper gates is made strong enough to hold up the water, assuming that the four other gates were destroyed. When the river is rising the sluices will all be open, and the red water will pass freely through, without depositing the fertilizing silt. After the flood when the water has become clear, and the discharge of the Nile has fallen to about 2,000 tons per second, the gates without rollers will be closed, and then some of those with rollers; so that between December and March the reservoir will be gradually filled. The reopening of the sluices will take place between May and July, according to the state of the Nile and the requirements of the crops. Between December and May, when the reservoir is full, the island of Philæ will in places be slightly flooded. As the temples are founded partly on loose silt and sand, the saturation of the hitherto dry soil would cause settlement, and no doubt injury to the ruins. To obviate this risk, all the important parts, including the well-known Kiosk, or "Pharaoh's bed," have been either carried on steel girders or underpinned down to rock; or failing that, to the present saturation level. It need hardly be said that having regard to the shattered condition of the columns and entablatures, the friability of the stone, and the running sand foundation, the process of underpinning was an exceptionally difficult and anxious task. It is impossible to estimate the far-reaching beneficial influence these irrigation works will bestow upon Egypt; but the reclamation of so many thousands of acres of desert for agricultural development cannot fail to improve the agricultural possibilities of the land, and assist Egypt to regain the prosperity it enjoyed in the era of the Pharaohs, with a greater cultivable area than it had even then. See Irrigation; Nile.

Assump'sit, in law, an action to recover a compensation in damages for non-performance of a simple contract; that is, a promise, whether verbal or written, not contained in a deed under seal. The word *assumpsit* (Latin) means, he undertook, and was taken as the name of this action from its occurrence in declarations, that is, formal statements of the plaintiff's cause of action, when these were in Latin. Assumpsits were of two kinds, *express* and *implied;* the former being where the contracts were actually made in word or writing; the latter being such as the law implies from the justice of the case; as, for instance, if one is employed to perform service or labor, the obvious justice of paying him a reasonable sum therefor when completed raises an implication, in law, of a promise to make such payment.

Assump'tion, a city in Paraguay. See Asuncion.

Assump'tion, a Church festival celebrating the translation into heaven of the Virgin Mary, kept on 15 August. The legend first appeared in the 3d or 4th century, and the festival was instituted some three centuries later. The story has been made the subject of a number of paintings by the most celebrated artists in history. The following are the best known: (1) Titian: in the Accademia in Venica; represents the Virgin being carried on bright clouds to heaven, surrounded by rejoicing angels, while the apostles look up from earth in amazement; (2) Titian: another painting in the Cathedral of Verona; (3) Correggio: frescoes in the cupola of the cathedral in Parma, Italy; (4) Rubens: painting in the cathedral at Antwerp, Belgium; representing the Virgin being carried to heaven, surrounded by angels, while several apostles and women are gathered at the empty tomb below; (5) Perugino: in the Accademia, in Florence; showing, in addition to the Virgin, four saints in the foreground; the representation of the Virgin is considered one of Perugino's most beautiful figures; (6) Guido Reni: a large canvas in Bridgewater House, in London; (7) Gaudenzio Ferrari: fresco in the Church of San Cristoforo, in Vercelli, Italy; showing figures of the Father, the Virgin, the angels, and the apostles; (8) Murillo: painting in the Hermitage Museum, St. Petersburg; representing the Virgin floating

Bird's-eye View of the Structure and Surrounding Region.

upward on clouds, with bands of cherubs above and below her; (9) Guercino: a painting, also in the Hermitage Museum; showing the Virgin, with uplifted face, being borne upward on a cloud, with angel attendants, and the apostles standing about her empty tomb. ‘The Assumption of Moses’ is the title of an apocryphal book, giving an account of the reception of Moses in heaven, written probably 20 A.D.

Assynt, ăs'ĭnt, a wild and rugged district of Scotland. There are inexhaustible quarries of marble, both white and variegated. Fresh-water lakes are numerous; the largest, Loch Assynt, is about seven miles in length and one mile in breadth.

Assyr'ia (the *Asshur* of the Hebrews, *Athurâ* of the ancient Persians), the ancient name of a portion of Mesopotamia, lying mainly between the Euphrates and the Tigris, the seat of the earliest recorded monarchy. In the earliest times it was probably limited to the low-lying tract between the Jebel Makloub and the little Zab (Zab-Asfal), on the left bank of the Tigris; but at its greatest extent Assyria must have been nearly 500 miles long, with an area of about 100,000 square miles. Toward the north Assyria bordered on the mountainous country of Armenia, which may at times have been under Assyrian dominion, but which at no time was considered as an actual part of the country. On the east dwelt numerous independent and warlike tribes, sheltered by the fastnesses of the Zagros Mountains. On the south Susiana or Elam was the frontier state east of the Tigris, while Babylonia occupied the same position between the rivers. West of Assyria lay Arabia, and higher up Syria and the land of the Hittites. The chief cities of Assyria in the days of its greatest prosperity were Ninevah, whose site is marked by the mounds opposite Mosul (Nebi Yunus and Koyunjik), Calah or Kalakh (the modern Nimrud), Asshur or Al Asur (Kalah Sherghat), Sargina, Khorsabad), Arbela (Arbil), etc. The surface of the country within its widest limits was of a diversified character. On the north and east the lofty mountain-ranges of Armenia and Kurdistan are succeeded by low ranges of arid limestone hills, occasionally enclosing fertile plains and valleys. Immediately south of this is a well-watered, productive, and undulating belt of country, into which run limestone rocks of a golden color, and wooded with dwarf-oak. This sinks suddenly down upon the great Mesopotamian plain (the modern El Jezireh), about 250 miles in length, interrupted only by a single limestone range rising suddenly out of the plain and branching off from the Zagros Mountains. The numerous remains of ancient habitations show how thickly this vast flat must have once been peopled; now, for the most part, it is a mere wilderness.

History.— Scripture tells us that the early inhabitants of Assyria went from Babylon, and the traditions of later times, as well as inscriptions on the disinterred Assyrian monuments, and the character of those remains, go to show that the power and civilization of Babylon were earlier than those of Assyria. In Genesis x. 11 it is mentioned that Nineveh was founded by Asshur, but for long the country was subject to governors appointed by the kings of Babylon. We learn from monumental inscriptions that about 1820 B.C., when Asshur was the capital of the country, Samsi-vul founded temples there to Asshur, the great national deity, and to Anu and Vul, besides a temple to the goddess of Nineveh in the city of that name. The Assyrian rulers gradually began to treat with their southern neighbors on equal terms, the boundaries of the two countries were for a time clearly marked out, and intermarriages among the reigning families occasionally took place. About the latter end of the 14th century Shalmaneser acquired the whole of Naharain (the country round the sources of the Euphrates and Tigris) by conquest, and planted Assyrian colonies there; he also founded the city of Kalakh or Calah, and restored the great temple at Nineveh. About 1300 B.C. he was succeeded by his son Tiglath-ninip, who conquered the whole of the valley of the Euphrates, and built or restored the palace at Asshur. The five following reigns were occupied with wars, more or less successful, with the Babylonians. About the year 1120 B.C. Tiglath-Pileser I., one of the most eminent of the sovereigns of the first Assyrian monarchy, ascended the throne, beginning his reign by the conquest of the Syrians and Hittites in the west. He then carried his arms far and wide, subjugating the Moschians, Commagenians, Urumians, and other tribes in the north; on the south he shattered the Babylonian power, and captured their capital. But this empire, acquired and ruled by the energy and genius of one man, began to fall to pieces at his death (1100). The period of decline lasted over 200 years, during which time little is known of Assyrian history. Under Assur-nazir-pal, who reigned from 884 to 859 B.C., Assyria once more advanced to the position of the leading power in the world. The extent of his kingdom was greater than that of Tiglath-Pileser, and the magnificent palaces, temples, and other buildings erected during his reign, with their elaborate sculptures and paintings, prove that wealth, art, and luxury must have reached a high stage of development. When he ascended the throne Nineveh was the capital of the kingdom, but he restored and beautified Calah, which had suffered during the troubled and declining years of the country, made it his favorite residence, and raised it to the dignity of the chief city of the state. Among the first acts of his reign was the suppression of a revolt by the Assyrian colonists of Naharain (883). This was followed by the victorious campaigns in Zamua on the eastern frontier (882–881), against several rebellious provinces in the northwest (880), and against the Shukhi or Shuhites, who then occupied a tract of country between Babylon and Assyria (879). In another expedition he crossed the Euphrates and advanced to the Mediterranean, near the mouth of the Orontes. In 859 Assur-nazir-pal was succeeded by his son Shalmaneser II., whose career of conquest was equally successful. The closing years of his reign were troubled by the re-

bellion of his eldest son, Assur-dain-pal, who had gained over to his side the cities of Nineveh, Assur, Arbela, and other important towns. After much fighting the rebellion was put down by Shalmaneser's second son Samsi-vul (Samas-Rimmon), who succeeded to the throne in 824. The old dynasty came to an end in the person of Assurnirai II., who was driven from the throne by a usurper, Tiglath-Pileser, in 745, after a struggle of some years. No sooner was this able ruler firmly seated on the throne than he made an expedition into Babylonia, followed by another to the east in 744. In the following year an alliance was formed against Assyria between Sarduri, king of Armenia, and several neighboring princes, and the Syrians came to their assistance at Arpad, on the Euphrates. Here they were defeated with great slaughter by Tiglath-Pileser, and the Armenian king was chased to the gates of his capital, Turuspa. The conqueror now advanced against Syria, overthrew the ancient kingdoms of Damascus and Hamath, and placed his vassal Hosea on the throne of Samaria. A protracted campaign in Media (737-735), another in Armenia, and the memorable expedition into Syria mentioned in 2 Kings xvi., are among the most important events of the latter years of his reign. Tiglath-Pileser was one of the greatest of the Assyrians; he carried the Assyrian arms from Lake Van on the north to the Persian Gulf on the south, and from the confines of India on the east to the Nile on the west. Yet he was not able to keep his seat on the throne, being driven from it by another claimant named Shalmaneser (727). Little is known of the five years' reign of this prince. He blockaded Tyre for five years, and on the revolt of Hosea, king of Israel, in league with Sabako, king of Egypt, he invaded Israel and besieged Samaria, but died before the city was reduced. His successor Sargon (722-705) claimed descent from the ancient Assyrian kings. At the very opening of his reign, after taking Samaria and leading over 18,000 people captive, he overthrew the combined forces of Elam (Susiana) and Babylon. In 719 Sargon turned his arms against the revolted Armenians, and in 717 he besieged and took the rich trading city of Carchemesh, which had also risen against his authority; here an immense spoil fell into his hands. In 716 the Armenians and several tributary princes in the north again took up arms for independence, but the Assyrians having again triumphed the Armenian king committed suicide and the other princes submitted. The attitude of Babylonia now began to look extremely dangerous. Merodach-Baladan, a Chaldæan leader, taking advantage of the troubles which closed the reign of Tiglath-Pileser, had possessed himself of Babylonia, and held it for 12 years, strengthening himself by alliances with Egypt and the various rulers of Palestine. In 710 Merodach-Baladan was driven out of Babylonia; in a single campaign the allies were crushed, Judah was overrun, and Ashdod leveled to the ground. Sargon spent the latter years of his reign in internal reforms, and in founding or beautifying several cities of his kingdom. A new city, called Dur-Sargina, was founded to the north of Nineveh, the library of Calah was restored and enlarged, and special attention was devoted to law reform. In the midst of these labors Sargon was murdered, and was succeeded by Sennacherib, one of his younger sons, in 705.

No sooner was Sennacherib seated on the throne than he was compelled to take up arms against Merodach-Baladan, who had again obtained possession of Babylon. In 701 fresh outbreaks in Syria led him in that direction. He first swept down on Zidon, drove the king into Cyprus, and seated Tubal on his empty throne. Next he deposed Zidqa of Askelon, and advanced against Ekron and Judah. The people of Ekron had dethroned Padi their king. and gave him into the hands of Hezekiah, king of Judah. The Egyptian and Ethiopian forces advanced to the assistance of their Judean allies, but Sennacherib totally routed the confederates at Altaqa in Judah, which he rapidly overran, taking 46 of its fortified cities. Hezekiah now submitted, agreeing to pay the conqueror a sum of 30 talents of gold and 800 talents of silver. Padi was given up and restored to Ekron, and after Sennacherib had chastised the rebels he returned to Assyria. The threatening aspect of affairs in Babylonia and Elam again called his attention to the south in 700, and in 699 he advanced to the northern boundaries of his kingdom to quell the insurrections which had broken out among the hill tribes. His second expedition into Syria is one of the most memorable in the history of Assyria, and is briefly recorded in 2 Kings xix. But his career of conquest was stopped by an appalling catastrophe: his army lay before Libna, when in one night "the angel of Jehovah went out and smote in the camp of the Assyrians 185,000 men" (2 Kings xix. 35). Sennacherib himself returned to Assyria, and occupied the last years of his reign in repressing the outbreaks of the Babylonians and Elamites, in constructing canals and aqueducts, and in entirely rebuilding Nineveh. In 681 he was murdered by his two sons, Adrammelech and Sharezer, but they soon found themselves confronted by a veteran army under Esar-haddon, their father's younger and favorite son, who defeated them in a battle at Kanirabbat, and assumed the crown (680).

Esar-haddon fixed his residence at Babylon, where he governed in person during the whole of his reign. The most important event of this reign was the conquest of Egypt, which left Assyria the mistress of the world. In 672 Esar-haddon led his forces into Egypt, drove out Tirhakah, its Ethiopian ruler, and divided the land into 20 separate kingdoms, the rulers of which were his vassals. Feeling unable to cope in person with his rebellious tributaries, Esar-haddon associated his son Assurbani-pal with him in the government of the kingdom (669), dying two years later. But constant wars were beginning to exhaust the men and treasure of the empire; and luxury, which had flowed suddenly in like a flood, was enervating the people. The king now no longer appeared at the head of his army, but intrusted it to generals, and abandoned himself to indolence and sensuality. Assurbani-pal was a zealous patron of the arts; learned men fom all countries were welcomed to his court; literary works were collected from all sources; the library of Nineveh was greatly augmented; the study of the dead language of Accad was encouraged, and dictionaries and grammars were compiled. The buildings were unrivalled for magnificence, his palace glittering with gold

and silver, and adorned with the rarest sculptures. Unfortunately the king's character was marked by cruelty and sensuality, and his example descended through the court to the people. He died in 625, and was succeeded by his son Assurebilili-kain, under whom Babylon definitely threw off the Assyrian yoke. The country continued rapidly to decline, fighting hard for mere existence until, under its last king Sarcus, Nineveh was captured and burned by the allied forces of the Medes and Babylonians in 606 B.C.

Ethnology, Language, Religion, etc.—The original inhabitants of Assyria and Babylonia belonged to that race variously called Turanian, Ural-Altaic, Scythian, or Tatar, and which appears at one time to have occupied the entire region from the Caucasus to the Indian Ocean, and from the Mediterranean to the delta of the Ganges. The ancient Assyrians, therefore, were of the same stock as that from which the Finns, Turks, and Magyars have descended; and their language, which has been preserved to us in inscriptions, and is known by the name of Accadian, is allied to the Ugro-Bulgaric division of the Finnic group of languages. The Akkadai or Accad race descended from the mountainous region of Elam on the east, and the origin of Chaldæan civilization and writing was due to them. In course of time, however, a Semitic race of people spread themselves over the country, and mingled with or supplanted the original inhabitants, while their language took the place of the Accadian, the latter becoming a dead language. Belonging to the Semitic family, these later Assyrians were thus members of the same great division of the human race as the Hebrews, Syrians, Phœnicians, and modern Arabians. The language differed little from the Babylonian, which was characterized by a preference for the softer sounds and a fuller use of the vowels. Both languages retained traces of the influence of the earlier Accadian. Assyrian is closely allied to Hebrew and Phœnician; it has their peculiarities of phonology, vocabulary, and grammar, and some obscure points in Hebrew etymology have been cleared up by its aid. The language changed little throughout the 1,500 years during which we can trace its career in the recently deciphered inscriptions. It continued to be written with the cuneiform character down to the 3d century B.C. Assyria could boast of but little native literature; it was a land of warriors, and the peaceful arts had their home in Babylonia. It was not until the time of Assur-bani-pal that any attempt was made to rival Babylon in learning. Their original works were for the first time composed, and treaties were composed even, in the dead Accad language. The greater part of the literature was stamped in minute characters on baked bricks, but papyrus was also used, although no books in this form have come down to us. The subjects of the Assyrian literature comprise hymns to the gods, mythological and epic poems, and works on history, chronology, astrology, law, etc. (See BABYLONIAN LITERATURE.) The Assyrian religion, like the language and arts, was in most essential points derived from Babylonia. There were the same gods, the same ceremonials and prayers, and even the temples had the same names. There is, however, in one point a notable difference. In addition to the worship of the Babylonian deities the Assyrians adored their national deity Assur, placing him at the head of the Pantheon. He was called king of all the chief gods, the god who created himself, it being supposed that he was self-existent and the creator of all things. After Assur come the 12 chief deities, Anu, god of heaven, ruler of angels and spirits; Bel, the father of the gods; Hea, king of the sea; Sin, or the Moon, lord of crowns; Shamas, or the Sun, judge of heaven and earth; Ninip, god of hunting; Nergal, god of war; Nusku, bestower of sceptres; Beltis, mother of the gods; Ishtar, leader of heaven and earth; and Bel, or Merodach, lord of Babylon. Most of those divinities had consorts, who were not, however, admitted to the first rank of the gods. Below this first rank were a number of spirits, good and evil, who presided over the minor operations of nature. There were set forms regulating the worship of all the gods and spirits, and prayers to each were inscribed on clay tablets with blanks for the names of the persons using them.

Art and Science, etc.—Although in art, as in other things, Assyria was the pupil of Babylon, there was yet a notable difference between its development in the two countries, due partly to two causes. The alabaster quarries scattered over the country supplied the Assyrians with a material unknown to their southern neighbors, on which they could represent, far better than the Babylonians on their enamelled bricks, the scenes which interested them. Sculpture was naturally developed by the one, just as painting was by the other, and the ornamentation which could be lavished on the exterior of buildings in Assyria had to be confined to the interior in Babylonia. The Assyrian artists, faithful and indefatigable, acquired a considerable power in representing the forms of men and animals, and produced vivid and striking scenes of the chief occupations of human life. If they did not strive greatly after the ideal, and never in this direction reached a very exalted rank, yet even here their emblematic figures of the gods have a dignity and grandeur which implies the possession of some elevated feelings. But their grand merit is in the representation of the real. Their scenes of war and of the chase, and even sometimes of the more peaceful incidents of life, have a fidelity, boldness, and lifelike appearance which place them high among the realistic schools. Unlike that of the Egyptians, which remained comparatively stationary from the earliest to the latest ages, the art of the Assyrians is plainly progressive, becoming gradually more natural and less uncouth, more lifelike and less stiff, more varied and less conventional. It may be said to have reached its highest stage of development in the reign of Assur-bani-pal, when it was characterized by great chasteness and softness, delicacy and finish. The beginning of Greek art coincides with the decadence of the Assyrian, and there can be no doubt that the Hellenic artists owe much to their Assyrian predecessors. The advanced condition of the Assyrians in various other respects is sufficiently evidenced by the representations on the sculptures, and by the remains discovered among their ruined buildings. We now know that they understood and applied the arch; that they constructed tunnels, aqueducts, and drains; that they used the lever and the roller; that they engraved gems in a highly artistic way; that they understood the arts of inlaying, enamelling, and

overlaying with metals; that they manufactured porcelain, and transparent and colored glass, and were acquainted with the lens; that they possessed vases, jars, and other dishes, bronze and ivory ornaments, bells, gold earrings and bracelets of excellent design and workmanship. Their household furniture also gives us a high idea of their skill, taste, minuteness, and accuracy. The cities of Nineveh, Assur, and Arbela had each their royal observatories, superintended by astronomers-royal, who had to send in their reports to the king twice a month. At an early date the stars were numbered and named; a calendar was formed, in which the year was divided into 12 months (of 30 days each) called after the zodiacal signs, but as this division was found to be inaccurate an intercalary month was added every six years. The week was divided into seven days, the seventh being a day of rest; the day was divided into 12 *casbu* of two hours each, each casbu being subdivided into 60 minutes, and these again into 60 seconds. Eclipses were recorded from a very remote epoch, and their recurrence roughly determined. The principal astronomical work, called the Illumination of Bel, was compiled for the library of Sargon of Agane; it was inscribed on 70 tablets, and went through numerous editions, one of the latest being in the British Museum. It treats, among other things, on observations of comets, the polar star, the conjunction of the sun and moon, and motions of Venus and Mars. The study of mathematics was fairly advanced, and the people who were acquainted with the sundial, the clepsydra, the pulley, and the lever must have had considerable knowledge of mechanics. See ASSYRIOLOGY.

Government.—Like all the ancient monarchies which attained to any considerable extent, Assyria was composed of a number of separate kingdoms. In the East conquest has very seldom led to amalgamation, and in the primitive empires there was not even any attempt at that governmental centralization which we find at a later period in the satrapial system of Persia. The Assyrian monarchs reigned over a number of petty kings, the native rulers of the several countries, over the whole extent of their dominions. These native princes were feudatories of the Great Monarch, holding their crowns from him by the double tenure of homage and tribute. This system naturally led to the frequent outbreak of troubles. See CUNEIFORM WRITING; NINEVEH; NIPPUR.

Assyriology. Assyriology may be defined as that department of study and investigation which embraces within its realm the country, people, languages, literature, and history of ancient Mesopotamia, Babylonia, and so much of adjoining countries as shared in the life of the Semitic valley-peoples prior to 538 B.C. The term is often popularly employed to cover a study of those languages written in the cuneiform script, or its immediate antecedents, the linear and picture methods of writing, current in primæval times in this great river valley. Such a delimitation of our theme would include a study of early Babylonia, Assyria, somewhat of Elam, and a mention of later Persia. Assyriology, therefore, deals with an antiquity which was centred in the great Babylonian valley, and embodied in the cuneiform languages.

Age.—This is a comparatively new department of research. It has been built up upon the basis of the discoveries of antiquities which have been made during the last three quarters of a century in the countries tributary to the Persian Gulf. The tentacles of this department reach out into every phase of ancient Oriental life and knowledge, and require of the modern investigator a comparatively comprehensive understanding of the complexities of that primitive life. This department includes in its sphere some of the most important of all branches of ancient lore. Among these we note especially Semitic philology, general archæology, architecture, sculpture, history, legend, so-called science, and religion. Assyriology has already taken its place as one of the great departments of human knowledge and research. The results of its investigations must now be reckoned with in any estimate of early Semitic legends, traditions, or history. Its importance to the student of the Old Testament is assuming greater proportions with each old site overturned by the spade of the excavator. The great museums of Europe and America count among their chief treasures the magnificent colossi, bas-reliefs, slabs, statues, and tablets that belong to the department of Assyriology.

Names.—The oldest of the governments represented in Assyriology is that centred in the Babylonian valley. Its earliest known mention at the beginning of the last century was that found in Genesis x. 10, where the beginning of the kingdom of Nimrod is said to have been Babel (Hebrew, בבל), probably the city of Babylon, "in the land of Shinar" (Hebrew שנער), a name for lower Babylonia. In post-exilic times the country was designated Chaldea, or "land of the Chaldeans" (Hebrew, ארץ כשדים), Ezek i. 3. Classical writers named this country after Babylon, that metropolitan city of their day, Babylonia, and this name is attached to it to the present time.

The next great country covered by Assyriology is Assyria. The Hebrews called it (Gen. x. 11) A'sshur (אשור), either the name of a personage or of a country, probably the latter. The translators of the Septuagint called it ασσουρ and ασσυριος, while Josephus, a couple of centuries later, refers to it as Ασσυρία. The Aramæans named it *Athur*, or *Athuriya*.

Boundaries.—The territory covered by ancient Babylonia was delimited on the west by the Arabian Desert, on the south by the Persian Gulf and Arabian Desert, on the east by Elamite territory backed up by the Zagros Mountains, and on the north by the uplands of Assyria. Assyria proper, in its early unexpansive period, was delimited on the east by the mountains of

Kurdistan, on the north by those of Armenia, on the south by Babylonia, with an ever-shifting boundary line, and on the west by the western limits of the Tigris valley and plain. In a word, Assyria was anciently seated in the upper Tigris valley, in possession of several great city-centres.

These two important countries were thus largely guarded by nature from foes on the south and southwest, but were always open to the intrigues of invaders from the east, north, or northwest. The historical records of these lands confirm this statement.

Description.—The great valley of Babylonia derives its marvelous fertility from its two notable rivers, the Tigris and Euphrates. Both have their rise in the mountains of Armenia, and both have their debouchement in the Persian Gulf. The Tigris, from its source, flows directly in a southeasterly and southerly course, cutting through the uplands of Assyria, and along the eastern side of the Babylonian valley, until, mingling with the waters of the Euphrates, it falls into the Gulf. The Euphrates, from its source, flows toward the southwest and bends southward within 100 miles of the Mediterranean Sea, and thence in general toward the southeast and south until, in union with the Tigris, it pours into the Gulf. These two arterial streams are the life of this great lower valley. By irrigation they were made to fertilize all their adjacent lands, and thus placed these among the richest countries on earth. In addition to water these streams bring annually from the mountains of Armenia great quantities of alluvia and deposit it in the lower valley. Geologists estimate that the shores of the Persian Gulf have been pushed southward, by deposits of this alluvia, fully 125 miles since the earliest periods of Babylonian history. In other words, the Tigris and Euphrates rivers that now enter the Gulf as one stream forming a vast morass, formerly had separate mouths, about 125 miles north of their present outlet. If this estimation be correct, the ancient Ur of the Chaldees (modern *Mugheir*) was practically a seaport city. The Tigris, being the shorter river, has a very swift current, and is less valuable for navigation than the Euphrates. Upon this latter stream vessels of profitable draft may ride to a distance of 800 miles above its mouth. The territory of Mesopotamia proper is watered by the Balikh and Khabur, two rivers that flow southward, emptying into the Euphrates. The region of Babylonia proper, though a waste to-day, shows marks of having supported a dense population in antiquity.

References to Ancient Peoples.—Present day students and scholars inferred from frequent references in the Old Testament and in the compiled works of Berosus, Manetho, Josephus, and others that this valley had been the headquarters of mighty nations. Classical writers carry echoes of an ancient glory won by great armies and powerful monarchs from the East, whose records were otherwise unknown, and whose mighty deeds seemed as unreal as fiction. The rise, conquest, and reign of these giant figures aroused the enthusiasm of every student of ancient history. The far-reaching influence and power over neighboring kings of these monarchs, dimly outlined in the vague second-hand records, set scholars to work. It drove them to search far and wide for other traces of peoples who had completely perished from the face of the earth, and who had, so far as they could see, left no story of their achievements. The reports of travelers who had passed through and spent some time in those countries attracted their attention.

Ancient Remains.—The entire territory drained by the two great rivers, Tigris and Euphrates, was found to be dotted by extensive mounds, ruins of ancient walls, piles of disintegrating towers, beds of ancient irrigating canals, and other marks of a once elaborate civilization. Travelers had often picked up near these mounds little bits of antiquities, bricks, tablets, and cylinder seals, that carried on their surfaces many curious wedge-shaped characters, which they regarded either as writing or ornamentation. These miscellaneous curios were thought to represent the civilizations of an unknown past, of peoples who occupied this territory in the days when prosperous cities and fruitful fields filled this great valley.

Earliest Excavations.—The first persons to take an active interest in the ruins of Babylonia and Assyria were Englishmen resident in some one of the chief cities of the country. C. J. Rich, a resident at Bagdad (1808–21), carefully examined and described several mounds, and some inscriptions, in small works published during his residence. The first systematic excavations within this valley were undertaken by P. E. Botta, French consul at the time in Mosul, a modern city of some commercial and political importance on the upper Tigris River, in 1842–5. He began work on the colossal mounds opposite Mosul on the east bank of the Tigris River; but he had little success until he transferred his force to the mound Khorsabad, about 14 miles north-northeast of the first site. Khorsabad proved to be an immense treasure-house of antiquities. Here he uncovered the stupendous royal palace of Sargon II. (722–705 B.C.), with a mass of inscriptions and antiquities of various kinds. This splendid find was greeted with enthusiasm by the scholarly world, and set minds to thinking and wills to acting to uncover other antiquities representing such a marvelous past. In 1845–7, A. H. Layard, an Englishman, began to dig at Nimroud, the ancient Calah, a mound about 20 miles south of Mosul, on the east bank of the Tigris. Persevering through almost indescribable difficulties, Layard finally succeeded in bringing to light the palaces of Assurnatsirpal (884–860 B.C.), Shalmaneser II. (860–825 B.C.), and Esarhaddon (681–668 B.C.). In 1849–51 this same intrepid excavator burrowed into the mound Kouyunjik, one of the mounds of ancient Nineveh, and lay bare two more great palaces, that of Sennacherib (705–681 B.C.), and that of Assurbanipal (668–626 B.C.). Botta's finds, so far as transportable, were taken to Paris and deposited in the Museum of the Louvre; those of Layard to the British Museum in London.

In this same period, Rassam, trained under Layard, made some valuable discoveries (1851–4) at Kouyunjik for the English; and Place at Khorsabad and Fresnel and Oppert at Hillah for the French. In most of the work undertaken by the English, Henry C. Rawlinson was a close adviser and an enthusiastic promoter.

Later Excavations.—The next 20 years (1854–73) were a period of cessation of excavations of any note. An occasional traveler or explorer found a few specimens of antiquities and

did a little desultory work. This 20 years, however, saw the publication of many notable works by Botta, Layard, Place, Oppert, and Rawlinson on the results of the active work of excavating and of inscriptions previously gathered out of the mounds. The second period of excavations began in 1873, when George Smith, of the British Museum, was sent by the London *Daily Telegraph* to the site of ancient Nineveh to find other fragments of the famous deluge tablet. Smith's phenomenal success in finding Assurbanipal's 30,000-tablet-library gave new life to archæological research, and sent him altogether on three expeditions, on the last of which he succumbed to a fever at Aleppo, 19 Aug. 1875. Smith's genius had presented to the world such representations of the important discoveries made by himself and others that the contagion spread, and other centres of scholarship turned their eyes toward the mounds of Babylonia and Assyria. Rassam was again called into requisition, and in 1877–8 gathered rich spoils on the site of old Nineveh, at Nimroud, and at Balawat, where he found the remains of the bronze doors of Shalmaneser II. (860–825 B.C.). In 1878–9 and 1880–1 he also found valuable relics on Babylonian ground.

From 1878 to the present day the French government has conducted excavations intermittently at Telloh, in lower Babylonia, for more than 20 years under the superintendence of E. de Sarzec, and recently under Capt. Crosman. This mound has yielded a rich store of antiquities, consisting of many thousands of tablets, of several beautiful diorite statues, of friezes, of palace plans, and of cylinders, many of which are deposited and mounted in the superb collection in the Louvre in Paris. The accompanying illustration presents two views of a part of the mound Telloh, where such notable discoveries have been made. The same government inaugurated and carried on excavations at Susa under M. and Mme. Dieulafoy (1884–6); and latterly under M. J. de Morgan, and has thus opened up new volumes on the history of ancient Elam, and its relations with adjoining countries.

A few broad-minded gentlemen, under the leadership of E. W. Clark, of Philadelphia, provided the means for the organization and prosecution of an expedition to Babylonia under the auspices of the University of Pennsylvania. This expedition was duly organized and equipped, and prosecuted work under the direction of John P. Peters, during 1888–90 at the mound Niffer, about 30 miles southeast of Babylon. Since that time the same institution has carried on work intermittently on this site, under supervision of H. V. Hilprecht, and, for the most part, under the field directorship of J. H. Haynes, has brought to light thousands of inscriptions and other antiquities. These have made the University of Pennsylvania the richest Babylonian-Assyrian museum in America.

Within the last decade German archæologists have joined the ranks of excavators, and have done some thorough work on several sites in the Babylonian valley, but chiefly at Babylon. The full results of their activity are still unknown to the public, as little has been published.

In 1904, the Oriental Exploration Fund of the University of Chicago was organized, and an expedition sent out under the direction of Robert Francis Harper, to excavate on the old site Bismya, in lower Babylonia. The first season's work justifies the hope that this may prove to be a fruitful mound, belonging to a high antiquity.

Outside of Babylonia proper, some notable discoveries of cuneiform inscriptions have been made by explorers. A stèle of Sargon II. was found in the island of Cyprus in 1845. There were found at Tel-el-Amarna, in Egypt, in 1887, more than 300 cuneiform tablets, which proved to be correspondence between the kings of Egypt and their Asiatic underlords and rulers in the 15th century B.C. Even Palestine has produced a couple of tablets in its excavated cities. Luschan found at Zinjirli, Asia Minor, among a host of Hittite antiquities, a statue and inscription of Esarhaddon (681–668 B.C.).

Decipherment of Inscriptions.—The neat little wedge-shaped characters, put together in so many combinations to form individual signs, very early attracted the genius of the linguist. As early as 1801, Grotefend, a German, discovered the significance of some of the old Persian cuneiform characters; and other scholars, following in his wake, likewise made some advance in identification of those old characters. But the long and sure step ahead was not made until Henry C. Rawlinson took up the problem. As an officer in the Persian army about 1835, he had unusual facilities for examining ancient ruins in that country. He observed at Behistun, in the Zagros Mountains, a rock stretching up almost 1,700 feet above the plain, and at about 350 feet above its base a large space carefully smoothed off. Upon this space was inscribed a mass of writing, distributed in several columns of varying length. After years of toil at intervals, he succeeded in copying the entire set. In a study of them he soon found that they contained three languages. The first, the Old Persian, through his knowledge of modern Persian and other related tongues, after years of study, he was able to decipher, and sent his translation to London, where, in 1847, it was published in the 'Journal of the Royal Asiatic Society.' Rawlinson's success was epochal, for it broke the seal into the hidden treasures of the cuneiform languages of Babylonia. His decipherment of one of the trilingual inscriptions opened the door into the next, the Susian. These two deciphered, scholars were soon able to penetrate the mysteries of the third language, the Babylonian-Assyrian.

These triumphs extended, roughly, over the years 1845–55. In 1857 the British Museum made a test of scholars' ability to decipher the Assyrian tongue. Four men, H. C. Rawlinson, Edward Hincks, Jules Oppert, and H. F. Talbot, were given a fine copy of a long historical inscription of Tiglathpileser I. (1120–1100 B.C.), and were requested to make each an independent translation of the text and report on their results. At a given time these scholars reported; and to the amazement, one should say, of all concerned, their translations were in substantial agreement from first to last. This was the crowning triumph of all in the eyes of other departments of learning. It showed that the riddle had been solved, that the Babylonian valley would henceforth speak for itself through its multitudes of ancient records.

Furthermore, this triumph of philology suc-

ceeded in placing in the galaxy of ancient nations some of the most powerful of peoples. Babylonia, Assyria, and Elam henceforth became the early home of vigorous nations, well-organized governments, conquering armies, and world-wide rulers. The ruin-covered wastes were suddenly transformed into fertile fields and prosperous cities, occupied by peoples whose influence touched the horizon of civilization in every direction. In short, this triumph of philology opened a door to a new world in southwestern Asia, prior to, and contemporaneous with, the times of the Hebrew kingdom.

Language.—The language in which this new-old material is preserved is the so-called Babylonian-Assyrian wedge-writing. Although the Old Persian is alphabetic, the Babylonian-Assyrian is a sign and syllable tongue. Each separate wedge ( ), or each combination of wedges ( ), constitutes a sign. This language was written by pressing the wedges with an instrument into clay or cutting them into stone or metal, for they never appear in relief. The primitive signs were probably rude pictures, which gradually grew through use into the form of curved and straight lines; these lines soon took on the artistic form of wedges. This evolution is seen in the fact that a large number of the signs possess merely an ideographic value; for example, we find a sign for the idea "land" ( ), "sun" ( ), "male" ( ), "female" ( ), "make," "fish," "king," etc. Some of these signs possess a syllabic value, as *da, ra, la, mat, lak, rid, zun, pad,* etc. Quite a number possess several syllabic values, the context being the reader's only guide as to which should be used in any given case. The reader's troubles are still more aggravated by the fact that the same sign sometimes has both ideographic and syllabic values. In this, as in the preceding case, the reader's tact must find in the context the reason for the reading which he should adopt.

There are about 600 independent and entirely distinct signs formed by combinations of anywhere from 2 to 30 wedges set together at different angles, or paralleled, or inserted within other combinations. But the great difficulties arise when we find that there were almost numberless combinations of anywhere from two to six different ideographic signs to express other and often compound ideas. There are nearly 20,000 such combinations known to-day to Assyriologists.

This Babylonian-Assyrian language is Semitic in character, though its soil is thought, by a large group of English, German, and French scholars, to be a non-Semitic tongue, the so-called Accadian or Sumerian. This question is prominently in the foreground to-day, due to the large accession of new material gathered at Telloh and Nippur, written in this ideographic tongue. The Babylonian-Assyrian tongue is a half-sister to the Hebrew of the Old Testament, and has already proved its real value in the interpretation of that book.

The People.—The peoples best known to Assyriology are Semites. The primitive inhabitants of Babylonia, the predecessors of the Semitic population of Babylonia and Assyria, were probably a mixture of various nationalities, with Semites in the lead. The group of scholars referred to in the preceding paragraph maintain that the predecessors of the Semites were Sumerians or Accadians, the inventors of the ideographic cuneiform language of those countries. We know, at least, from inscriptions found at Nippur, that the Semitic language was in use in Babylonia as early as the fourth millennium B.C. The population of Babylonia and Assyria in historic times was Semitic. Their location made them warriors, for they had to be perpetually on the defense. The Babylonians cultivated the peaceful arts and were wide awake to the best things of life in their time and day. The Assyrians, on the other hand, built up an engine of warfare, a tremendous military machine, that, under powerful leaders, beat down and overthrew nations on every hand. Some one has compared Babylonia and Assyria to Greece and Rome respectively, as fostering and furthering different elements of national life and character.

The Civilization.—One of the marvels of these ancient peoples was their advancement in all that counts for civilization. Their governments were monarchical and well organized, with standing armies for their immediate protection. Their civil courts were provided with ample laws for the regulation of society and of trade. Their cities were advantageously built, and surrounded with walls of a magnitude sufficient to withstand any ordinary attack. Their schools were carefully fostered and occupied a first place in their peaceful life. They cultivated the arts with assiduity and attained a notable degree of perfection in some lines. Their architecture and sculpture, their language and literature, are marks of a people high in the scale of Oriental civilization. Of religious ritual and all its accompaniments and organization, we have a detailed description, which exhibits this as a favorite side of that early Semitic life. Their industry and trade activities were such as to place them in the front rank of commercial peoples. Their amusements and sports were of that adventurous and daring kind that bespeak the virility and strength of character found only among a hardy and vigorous people. Their political and commercial relations with their neighbors were such as mark an advanced stage in cordial international affairs. Their methods of warfare, and their treatment of their subjects, while often cruel and inhuman, were distinguished by a high grade of intelligence, and more than ordinary genius.

Natural Resources.—The wasteness and barrenness of modern Babylonia give little intimation of its early resources. Its flora was quite varied and useful. Its plains were plentifully supplied with fruit trees of various kinds, such as fig-, olive-, date-palm-, vine-, and various nut-trees. On the mountain sides were found the oak, plane, and pine trees of different varieties. By cultivation the land produced wheat, barley, sesame, millet, hemp, and other cereals and articles of commerce. The date-palm was their universal utility article, for from it they seem to have manufactured honey, flour, vinegar, wine, and raw material for wickerwork. The reed that grew with such luxuriance on the banks of the rivers and canals was utilized for a number of purposes. It served for building huts, weaving mats, and for boat-building, and

for layering mortar in the construction of walls.

The absence of stone and minerals in the basin of the valley was partially compensated for by their proximity to the mountains on the north and east, though clay bricks, sun-dried and burnt, were always their chief building material. When marble, alabaster, diorite, or any of the precious metals were used they were brought either from their mountain borders or from distant lands. Stone was used for colossi, statues, wall decorations, bas-reliefs, and some inscriptions. The precious metals were employed for making jewelry, ornaments, serviceable utensils, decorations on buildings and gates, and for tablets upon which inscriptions were engraved.

The list of the fauna of the country is made quite complete by the pictures found on the walls of the old palaces and temples, and by the catalogues of names preserved in their literature. These reveal to us a great variety of valuable animals. Among them we find the lion, the favorite game hunted by kings, the panther, the wild ox, the fox, the wild boar, wild asses, and camels — especially in later periods of history. There were also several kinds of gazelles and antelopes that played about on the border hills and mountains. Of domestic animals, there were the horse in later times, the ass, the camel, the cow, sheep, goat, and dog. Of wild birds, the inscriptions mention most frequently the eagle and the owl; also the swallow, dove, raven, geese, and other waterfowls.

Cities.—There is no more notable index of a great people than the number and magnitude of its great cities. Babylonia-Assyria, through the decipherment of the monuments, is seen to have been well dotted over with prosperous cities. Beginning in the south and proceeding northward, we find in that ancient day, Eridu, Ur, Erech, Larsa, Lagash, Nisin, Nippur, Borsippa, Babylon, Cutha, Sippar, and Agade (!)— all famous cities in the Babylonian kingdoms and empires of four millenniums ago. The earliest civilization of that valley was centred in these cities, most of which seem to have been originally capitals of districts. There are other mounds in considerable quantity that have not been identified, but which doubtless cover still other cities that played an important role in the life of early Babylonia.

As we advance into the territory occupied by Assyria great cities present themselves in a formidable array. The ancient mother city of Assyria was Ashur, located on the right bank of the Tigris, near the modern *Kalât Sherkât*, now being excavated by a German expedition. As we pass up the Tigris River of that day the next city of importance that one meets is Calah, or Nimroud, on the left bank of the river, just above the junction with the Tigris of the Upper Zab River. This was a palatial city, first unearthed by Layard, and then by Rassam, containing at least three royal palaces already mentioned. Off to the east of Calah, on the east bank of the Upper Zab, was Arbela, a minor city of importance. Nineveh, whose mounds stand on the eastern bank of the Tigris opposite the modern Mosul, was a very ancient city. The small stream or river *Khosr*, passing between the two great mounds Kouyunjik and Nebi Yunus, that represent the remains of Nineveh, empties into the Tigris. Sargon II. (722–705 B.C.) built for himself at Khorsabad, north of Nineveh, a veritable royal city, the most magnificent building of which was his palace, uncovered by Botta and Place. Its name, Dur-Sargina, "the wall or fortress of Sargon," designates sufficiently its significance for his reign. To the southeast of Nineveh we find another city of especial significance in the reign of Shalmaneser II. (860–825 B.C.), Imgur-Bel, on the site of the modern *Balawat*.

Adjacent to this valley were such mighty cities and fortresses as Susa in Elam, Harran and Reshini in upper Mesopotamia, and Carchemish, with other cities on its western frontier — all evidence of the thrift and permanency of the civilization of 3,000 and 4,000 years ago.

Architecture.—The buildings of Babylonia-Assyria were modified architecturally, no doubt, by the character of the material accessible for their construction. Throughout this entire valley the absence of stone led to the use of clay bricks, sun- and kiln-dried, for building material. This, of course, necessitated a plainness of form that admitted of little exterior decoration. The walls were often built very thick, of sun-dried, with a veneer of kiln-dried, bricks. This veneer was a protection against the ravages of the weather, and the depredations of robbers, who could readily dig through a thick wall of merely sun-dried bricks. The strength of a sun-dried brick wall was sometimes increased by inserting between the courses of bricks layers of reeds. The entire structure was built on an artificially raised mound, primarily to lift the building above the danger of the overflowings of the rivers, but later apparently because of the age-long custom of placing it on an eminence. The entrances to the palaces and temples were usually guarded by great monolithic colossi, human-headed bulls or lions, standing on each side and facing outward. Within were courts of different sizes that served the royal personages or their attendants. In immediate connection with each palace or group of royal buildings, particularly in Babylonia, was the tower or temple. It was a structure that towered above everything else, and rose from its base to its summit in a series of stages, sometimes seven, or steps, by which one ascended. On the top of this massive pile one would find the image of the god held in particular reverence, or to whom the tower was dedicated. There are several remains of these sacred structures found in Babylonia to-day. Their ability to withstand the ravages of time is due to the hard burnt bricks with which they were constructed. The remains of the tower at Mugheir, the ancient "Ur of the Chaldees," was built, according to its present indication, upon a platform 20 feet above the plain; its base was a parallelogram about 200 feet by 135 feet.

One of the niceties of these constructions was their adaptation to the necessities and comforts of the people. There was an admirable system of drainage, of hydraulics in general, that embodied some of the best principles of modern sanitation. The arch contributed no little to the construction of some of the primitive royal buildings of the 20th century B.C.

Sculpture, Engraving, etc.—The most precious contents of the temples and palaces were the statues of the gods and kings, respectively.

BLACK DIORITE STATUE OF GUDEA FROM TELLOH *(after de Sarzec)*

(ABOUT 2800 B.C.)

(NOW IN THE LOUVRE, PARIS)

They are the best specimens of the sculpture of the Babylonian-Assyrian peoples. These works of art were often chiseled out of diorite, as those found by the French at Telloh, out of alabaster, as many of the giant colossi, or out of a basaltic rock, or black marble. The sculptors, even as far back as 3000 B.C., executed some wonderful work. Even more striking and complicated were their bas-reliefs, found so numerously on the walls of the palaces of the Assyrian kings. In this species of art there is often superb genius displayed in the introduction of many figures, of warriors, war-chariots, cavalry charges, battle scenes, sieges and captures of cities, and divinities of various grades. But in all these representations the modern student must not be disconcerted because of the lack of perspective. This is one of the characteristics of all early relief work and painting, and must be reckoned with in our study of those times.

Besides the large and imposing works of art, there were numerous small objects that occupied large attention and revealed some real artistic skill. There were the silver vases of the time of Entimena (about 3800 B.C.), ivory objects showing exquisite workmanship, gold ornaments, cylinder seals reaching back to 4000 B.C., of many precious stones whose intaglio work would be a credit to this day. The method of executing such fine work on the hardest of precious stones is still a puzzle to modern engravers. The decorations of Assyrian and Persian palaces include also painting, though of a kind that reveals more crudeness than the specimens of the engraver's art.

Literature.—The discoveries of the last three quarters of a century have opened for us the doors to a new library of ancient Oriental literature. These clay and alabaster volumes cover a large range of subjects, and treat them in a manner entirely unique. The first that attracted attention was, of course, the immense amount of historical matter, found mainly in the ruins of Assyria. Another large element in these tablets, particularly in Babylonia, is the poetry, pure Semitic poetry, or interlineated with so-called Sumerian poetry, whose character is determined by the presence of parallel members. This poetry contains hymns to the gods, penitential psalms, incantations, magical formulæ, and even epics of surprising strength. Examples of this poetry in Assyria were copied from Babylonian originals, as Assyria was notably weak in its literary ability. Then there are legends, mythology, and popular treatments of technical subjects. We find also treatises that are geographical, biological, geological; tablets that are commercial in character, recording loans, deeds, rents, and trades; long lists of matter that is purely linguistic, for it deals with signs and their values; a codified system of laws that touched almost every complication in the complexities of Babylonian life; letters, domestic and international, that reveal both the home customs of the nation and their foreign relationships and authority.

Myth and Legend.—The poems that are sometimes called epic, in the literature of Babylonia, are based upon events that are usually termed mythical. The epic and mythical elements are so thoroughly commingled that the entire narrative may be termed mythological. The scenes depicted are those between gods and gods, and between gods and men, and other creatures. The most famous stories classified as mythology are the so-called creation epic, the epic of Gilgamesh, of which the eleventh tablet or poem is the Babylonian story of the deluge. There are several legends and fragments of legends which have received careful study in recent years, whose matter is arranged on the customary Babylonian poetical plan. Some of these are, the descent of Ishtar into the world of departed spirits, the Namtar legend, the Adapa and Etana legends, and legends of various gods. Some of these entertaining literary stories take their place for real merit and interest beside the best legendary lore of ancient Greece. Their archæological value is often considerable, and their relation to the religious life of Babylonia-Assyria immeasurable.

Religion.—The primitive religion of Babylonia was doubtless the worship of the different powers of nature. These became personified and everything that took place in the world was simply the result of the action of some particular god, who stood above man in the scale of being, and executed all movements in the especial sphere where he was supreme. The representatives of these divinities on the monuments are seen sometimes to be men, and at other times to be part man and part beast and bird. Those in the form of men possessed attributes like, but far superior to, man. Since they represented different powers in nature, none of them was all-powerful. Their functions lay in special lines, and for these they were worshipped. In Assyria, the gods as a whole were practically borrowed from Babylonia. But Asshur, the great divinity of Assyria, stood alone, unique in all the Mesopotamian pantheon, and supreme in Assyria. The chief gods of Babylonia, those that were supreme in its pantheon, were three, Anu, the god of heaven, Bēl, the god of the earth, and Ea, the god of the abyss and of secret knowledge. These great three were followed by another triad, who regulated light and the weather, namely, Shamash, the sun-god, Sin, the moon-god, and Ramman, the weather-god. These six divinities were localized, in that each was the patron deity of some city. For example, Anu was the patron deity of Erech, Bēl of Nippur, Ea of Eridu, Shamash of Larsa and Sippar, and Sin of Ur (of the Chaldees). There is a long list of other gods and goddesses, who were doubtless related to the two chief triads, but up to the present time this relationship in all cases cannot be determined. Slightly aside from the lists already named we find the great goddess Ishtar, one of whose feats is described in the legend, 'Descent of Ishtar.'

Worship.—The cities of Babylonia-Assyria were well supplied with temples, in which the gods were devotedly and assiduously worshipped. Indeed, this worship was an essential element in the life of the Babylonians, to a greater extent than among the Assyrians. The temples were the most elaborate buildings of Babylonia, and were under the immediate direction of the priesthood, the most powerful class of men, next to the king, in the nation. Babylonian inscriptions, particularly, enumerate many temples in the chief cities that were dedicated to the patron deity of each several city. Each temple had an organization of official priests, whose duties

were the preservation and propagation of the worship of the god of that temple, and the ritual and traditions thereof. The king was the great overlord or guardian of the temple, and spared no means to keep it in a thoroughly good state of preservation, and to increase its popularity among his subjects. The support of the priesthood was provided for by revenues produced by the lands attached to the temple, or belonging thereto, supplemented by regular offerings. These priests, as those in Egypt, were the most influential men in the kingdom, for they controlled the religious life of the community, and had no small part in the affairs of political and civil life. They were probably the best educated men in the nation, and by their learning filled the offices that required a somewhat broad training, such as scribes, historians, and librarians.

The regular duties of the priests in connection with the temple service were (1) to officiate at all the regularly appointed services of the temple, including the monthly and annual set feasts, and (2) to carry out the worshipful desires of any individual worshipper. The minutiæ of conditions regnant in temple service are voluminous, and touch almost every condition of life. Some of the incantations and psalms, already referred to, preserve the petitions that must be recited by the suppliant. Other tablets enumerate the great variety of offerings that must be presented to the gods to secure their good-will and blessings. The multiplicity of such requirements easily kept an army of priests busy in the great temples of the principal cities of Babylonia-Assyria.

Sources of Babylonian-Assyrian History.—Before the excavations of the last 75 years in the ruins of Babylonia-Assyria, the two main sources of the history of the peoples and country in our theme were (1) the books of the Old Testament, and (2) the second-hand narratives of Berosus, Manetho, and Josephus, with a few scattered statements and some questionable narrative in Greek and Roman writers. The discoveries in the ruins of Mesopotamia have now given us first-hand information of the best kind, narratives just as they were written down by the original scribes, and not copies made from age to age, as are the works above referred to. These clay, stone, and metal records stretch not continuously as yet, but with breaks here and there, from at least 4000 B.C. down through the fall of Babylon before the army of Cyrus 538 B.C. Of course, they cannot be regarded as infallible, but are still for our purpose reasonably reliable. They give us, at least, a new panorama, of the most vivid kind, of the great nations that moved down the avenue of time in Babylonia for nearly 4,000 years.

Chronology.—The chronology of Babylonia must be described in part separately from that of Assyria. The early Babylonians reckoned events from some great calamity or occurrence, such as the destruction of a city, the dedication of a temple, or the opening of a new irrigating canal. Later down in the history they counted time by the years of a reigning king. The "List of Kings," a list of the kings (not complete) of Babylon from about 2400 B.C. to 625 B.C., by dynasties, with the length of reign of each king and of each dynasty, and the so-called "Babylonian Chronicle," consisting of a record of events in Babylonia and Assyria from about 745 B.C., early in the reign of Nabonassar, to 669 B.C., the beginning year of the reign of Shamash-shum-ukin are valuable documents. The Ptolemaic Canon, which has some reliable features, also begins with Nabonassar's reign. Besides these guides there are references here and there that both serve as checks and give us fixed points from which and toward which we may figure. One of the most striking is that mentioned by Nabonidus (555–538 B.C.) on one of his cylinder inscriptions. He there states that an inscription of Sargon which he found in the corner-stone of a temple had been deposited in its hiding place 3,200 years before his day, or about 3750 B.C. The more we find of ancient Babylonian facts the more probable the correctness of this date seems to be. Then there are chronological notes and hints, such as the statement that Burna-buriash lived 700 years after Hammurabi, that Marduk-nadin-akhe defeated Tiglathpileser I. 418 years before Sennacherib conquered Babylon. Each such hint furnishes a valuable check on the whole chronological scheme, and aids the scholar in his construction of a valid and reliable list of rulers and events, even though for the present there are some wide and embarrassing gaps in the period covered by Babylonian history.

Assyrian chronology follows a unique plan. It names the years after certain officers, termed eponyms, whose term of office extended over but one year. Lists of these eponyms have been found stretching from 893 B.C., during the reign of Adad-nirari II. (911–890 B.C.) down to Assurbanipal (668–626 B.C.). On some of these lists we find merely the name of the eponym, on others there is found the name of the king in authority, in fact he usually was an eponym at some time during his reign, and some of the chief events of each year. The succession of events between the limit years mentioned above is now positively known. To verify our calculation that these Assyrian records are correctly poised in time, we find that in the month of Sivan, year of eponymy of Pur-Shagalti, there was a total eclipse of the sun in Nineveh. Astronomers have located this same eclipse on 15 June 763 B.C., thus giving us a fixed point for our calculations, and for settling specifically the dates of the entire Assyrian eponym lists.

Historical Periods — Babylonia.—The history of Babylonia may be roughly divided into three periods: (1) That stretch of time reaching from the remotest recorded events down to the time of the consolidation of the kingdoms of Babylonia under Hammurabi at Babylon, about 2250 B.C.; (2) the time included between Hammurabi's supremacy and 626 B.C., the death of Assurbanipal, last great king of Assyria, and the rise of Nabopolassar, first king of the new Babylonian kingdom; (3) beginning of Nabopolassar's reign (625 B.C.) to the fall of Babylon before Cyrus (538 B.C.).

First Period — Babylonia.—The beginnings of this period are enveloped in fog. Scattered fragments of antiquities and archaic inscriptions tell a broken tale of a very remote antiquity. Telloh, Nippur, Babylon, and Susa have yielded to the excavator many evidences of an extreme antiquity, and have put into our hands material for beginning to estimate some of the elements of such early civilizations. Some of the earliest

kings were those who ruled over Erech and Lagash, which occupied territory apparently on the north and south side, respectively, of the irrigating canal, *Shatt-el-Hai*, connecting the Tigris and Euphrates rivers. Other kingdoms in this early period, apparently earlier than 4000 B.C., were Kish and Ur. The formal name of a governor in this earliest age was *patesi*. Lugal-zag-gi-si, however, king of Erech, apparently a Semitic name, designates himself "king of Erech, king of the world," but calls his father Ukush, "*patesi* of Gishban." Other kings of this very early period were Ur-Ninâ, the foundations of whose palace at Telloh are to be seen in the first illustration, and E-dingirrâna-du. E-dingirrâna-du was a *patesi* of Lagash and a victorious ruler, who seized and maintained authority, among others, over Gishban, Kish, Erech, Ur, and Larsa. These events must have occurred about 4000 B.C.

About 3750 B.C., according to the reckoning of Nabonidus, already mentioned, we find Sargon I. in power, swaying his sceptre to the westward as far as the shores of the Mediterranean Sea. His son, Naram-Sin, carried on the extensions of his father's kingdom until he included in his realm northern Syria, northern Arabia, Mesopotamia, and Elam. He designates himself, therefore, "king of the four quarters of the world." There is a break in the records at this point. The next ruler, rather *patesi*, of Lagash apparently inaugurates a new reign, that enfolds within its borders the sway of all southeastern Babylonia, including also Elam. This *patesi* was Gudea, one of the most famous rulers of this valley, at about 2800 B.C. The accompanying cut represents one of his inscribed statues of block diorite found at Telloh, around which we find 366 lines of writing very artistically cut into this hard stone. On the lap of the statue there is a plan of a building, designed in exact proportions, revealing the measurements current in Gudea's day. His numerous inscriptions tell us of his world-wide commercial activity, though his political power may not have included more than Elam outside of Babylonian territory. The power of the *patesis* of Lagash stretched over some time, and was a distinct force in the civilization of lower Babylonia. We have also the names of several kings of Ur, of Nisin, of Erech, of Larsa, and of some smaller cities, whose exact location in the chain of history is not as yet fixed.

Second Period — Babylonia: First to Third Dynasties. Beginning of Assyria.—The isolated kingdoms of Babylonia had already existed for centuries, with here and there a ruler who had been able to gain the supremacy over one or more of his neighbors for a time. But the man above all others who unified these scattered realms under his own sceptre, with Babylon as a centre, was Hammurabi, whose long reign of 55 years began about 2285 B.C. He greatly improved the internal condition of his own country, both materially and politically, and carried his conquests to Elam, as had Sargon I., his predecessor by 1500 years. Hammurabi's influence and power for the welfare of his subjects have been brought out anew by the discovery at Susa, in December 1901–January 1902, by M. J. de Morgan at the head of the French expedition, of a code of laws which had been compiled under his direction and orders. This remarkable document shows that Hammurabi's government was thoroughly regulated, for it provides laws now intact to the number of 243 to govern the complexities of commercial, social, and official life. Successive kings of this first dynasty, founded about 2400 B.C. by Sumuabi, are known as yet but slightly, though many contract tablets belonging to this period have been found.

The second dynasty in the "List of Kings" consists of 11 rulers, about whom we know nothing. It is thought that during their reign the Kassites made their way into Babylonia from the countries of Media and Elam and secured a hold on the throne.

The third dynasty in the "List of Kings" is made up of 36 kings, but only a few names at the beginning and at the close are preserved. The "Synchronous History," however, supplements this *lacuna* in some respects, and gives us an idea of the relations of this dynasty to Assyria. In fact, early in this dynasty the former little colony of Assyria, which had migrated from Babylon some time about 2500–2300 B.C., rebelled against its mother-country, Babylon, and secured its independence. Its first king of whom we know the name was Bēl-Kapkapu, mentioned by Adad-nirari III. as an early king on the Assyrian throne. Ashur-bēl-nishishu is the first king about whom we know anything of value. He ruled about 1480 B.C. and was on friendly terms with Kara-indash, a king of the third Babylonian dynasty. Several successive Assyrian kings seem to have perpetuated this friendship, but jealousy and hostility sprung up and there were, repeatedly, clashes of arms, in which, on the whole, the young and vigorous Assyrian kingdom was victorious. One of the notable Assyrian kings of this period was Shalmaneser I., who ruled about 1330 B.C. His great campaigns against the territory northwest of Assyria are celebrated in the records of Assurnatsirpal (884–860 B.C.).

Second Period — Babylonia: Fourth to Seventh Dynasties. Assyria, 1120–1075.—The fourth Babylonian dynasty is called the dynasty of Pashe. We are not aware of the name of its founder. The "List of Kings" is, unfortunately, mutilated so that we have only portions of the names of the last three kings. The "Synchronous History" fills part of the gap by giving some of the relations between Babylonia and Assyria during the life of this dynasty. These relations were hostile in some of its earlier years, when Nebuchadrezzar I. was on the throne, and the battle went against the Babylonians. Then Marduk-nadin-akhe, a Babylonian king, wrested victory from the Assyrians. Tiglathpileser I. (1120 B.C.), king of Assyria, on the other hand, completely routed the same Babylonian king, captured a number of cities in North Babylonia, and even Babylon itself. Succeeding kings of this Babylonian dynasty and of Assyria made treaties of peace, and for the time being ceased their wasteful warfare. Of all the Assyrian kings who reigned in the time of this Babylonian dynasty, Tiglathpileser I. was the most vigorous, aggressive, and successful. His example furnished an inspiration for all succeeding Assyrian rulers, and his conquests, related in full in his cylinder inscription, give us a fine specimen of early Assyrian historical writing.

The fifth Babylonian dynasty (about 1050 B.C.) consisted of three kings and was very short. It has been called the "Sea-land" dynasty, because it is thought probable that the Chaldeans about the head of the Persian Gulf were the occupants of the throne. At least, it is probable that the country was in political confusion during the life of this dynasty.

The sixth dynasty (about 1025 B.C.) was that of Bazi, and, like its predecessor, had just three kings, of whose acts very little is known.

A gap of about 100 years is found at this place in our sources, a part of which is attributed to the unknown seventh dynasty — possibly an Elamite, which is said to have ruled six years.

Assyrian history likewise has a gap of more than 100 years (1070–950 B.C.). The "Synchronous History" leaves us in the dark in this period.

Second Period — Babylonia: Eighth Dynasty. Assyria about 930–783 B. C.—The eighth dynasty of Babylon is supposed to have been native Babylonian, and occupied the throne from about 1000 to 800 B.C. The kings who ruled in Babylon during these 200 years fought a losing battle with the Assyrians, for in almost every clash the Assyrian was victorious. Though the names of the early kings of this dynasty are lost, we know those of the kings who waged war with Assyria during the larger portion of the life of the dynasty. With this dynasty the "Synchronous History" closes.

The Assyrian records, the "Eponym Canon," begin in this period, at 893 B.C., and give us a continuous annual list down to 666 B.C. One of the most notable Assyrian kings of this period who have left us their records was Assurnatsirpal (884–860 B.C.). This king was one of the most energetic and aggressive monarchs of Assyria. He established Assyria's authority in every direction, even to the coasts of the far-off Mediterranean Sea. His reign was vigorous, cruel, and even barbaric. Locally, he built a great palace at Calah, and one at Nineveh, and restored the temple of Ishtar at the latter place. His son, Shalmaneser II. (860–825 B.C.), still further extended the limits of his paternal realm by including lakes Van and Urumiyeh, in Armenia, and becoming protector of Babylon. To students of the Old Testament his reign assumes more than ordinary importance, for he was the first Assyrian king to come into contact with the Hebrew nation of Palestine. He mentions "Ahab of Israel" and "Jehu, son of Omri," both of whom became his subjects in the Westland. The accompanying illustration presents four of the five reliefs on one of the four sides of the famous Black Obelisk of Shalmaneser II. These four represent the tribute paid by four foreign countries to the Assyrian king. The inscription over the first relief reads: "Tribute of Sûa of the land of Guzan, silver, gold"; over the second: "Tribute of Jehu, son of Omri, silver"; over the third: "Tribute of the land of Mutsri, double-humped dromedaries"; over the fourth: "Tribute of Merodach-abil-utsur of the land of the Sukhites." These four reliefs and inscriptions are only the first of four, the other three being found on the other three sides of the obelisk. Shalmaneser's son, Shamshi-Adad II. (824–812 B.C.), succeeded him on the throne, and rescued the kingdom from a rebellion which had been stirred up by a brother. His only notable conquest was over Babylon under command of King Marduk-balatsu-ikbi.

The next king of Assyria was Adad-nirari III. (812–783 B.C.), son and successor of his father. His was a prosperous reign, reaching to Tyre, Sidon, Palestine, and Philistia. Even Mari', king of Damascus, yielded submission to his sway.

As in Babylonia, so the next rulers in Assyria, three in number, amounted to little.

Assyrian Supremacy: Tiglathpileser III. Babylonian Subjection.—Assyria's three lethargic rulers between 783 and 745 left no records that deserve mention. But their great successor, Tiglathpileser III. (745–727 B.C.), redeemed the ancient reputation of the empire. This new king, although a usurper, revolutionized the policy and methods of the Assyrian empire. He pushed out the boundaries of Assyria farther than any predecessor on the throne. He completely subdued Syria, Palestine, and Philistia. According to his own records, he, more than any other Assyrian monarch, came into close contact with the Hebrews. He mentions Menahem, Pekah, and Hoshea, kings of the northern kingdom, and Uzziah and Ahaz, kings of the southern kingdom. To him also is to be attributed the policy of deportation of captives from a given district, and importation into that same district of peoples from distant districts, in order thereby to prevent the possibility of uprisings and rebellion. He also inaugurated a kind of local self-government, or provincial districts, as parts of his administrative policy, thus making a decided advance over the reign of his predecessors.

The next Babylonian king of whom we know anything of consequence is Nabonassar (747 B.C.), mentioned in the Canon of Ptolemy, as well as in the "List of Kings" and the "Babylonian Chronicle." But from this time down to the rise of the new Babylonian empire, Babylon was everywhere practically in the hands of Assyria, though there were some sanguinary struggles for the supremacy.

Sargon II. (722–705 B. C.).—Tiglathpileser's successor was Shalmaneser IV. (727–722 B.C.), about whom we know little, as none of his inscriptions have been found. His one act of note was the siege of Samaria in 724 B.C. His successor was Sargon II., whose first act was the capture of Samaria in 722 and the deportation of the Jews to various parts of his empire. This Sargon was a master ruler, who not only subdued and held in subjection the peoples on the east coast of the Mediterranean Sea, but also with indefatigable skill put down Merodach Baladan of Babylon and his attempted conspiracy (cf. Isa. xxxix.). Sargon's great home achievement was the construction of that colossal palace at Khorsabad, just north of Nineveh, that was first discovered by Botta in 1842, as already described.

Sennacherib, 705–681 B. C.—Sargon II. was assassinated in his new palace at Khorsabad in 705 B.C. and was succeeded by Sennacherib, his son. This vigorous ruler conducted at least three successful campaigns: (1) against the Westland: Syria, Phœnicia, and Palestine (701 B.C.), when he overran Judah, carried off 200,150 captives, threatened Jerusalem, making Heze-

kiah his subject, and met and, according to his own records, defeated an Egyptian army at Elteku; (2) in an expedition against Elam (693 B.C.) he was only partially successful, not quite reaching the capital, Susa; (3) in 689, he sacked, burnt, and practically destroyed the city of Babylon, in revenge for the rebellious acts of its former ruler and inhabitants. Sennacherib removed the capital from Calah to Nineveh, and erected for himself a magnificent palace in that newly made capital of the unified Assyrian-Babylonian empire. Other public works of an extensive nature, such as arsenals and water supply, were the objects of his energy. Sennacherib was murdered by one of his sons, according to the "Babylonian Chronicle," and was succeeded by Esarhaddon, his son, who was not engaged in the conspiracy.

Esarhaddon, 681–668 B. C.; Assurbanipal, 668–626 B. C.—Sennacherib's son, Esarhaddon, carried on a successful warfare against the mountaineers to the north and northeast, and was the first Assyrian ruler to carry his conquests into Egypt. In 671 B.C. he crossed the frontier of that age-old land, took Memphis, and carried his arms as far as Thebes, driving the Ethiopian monarch of Egypt, Tirhakah, back into his homeland. He was the first king of Assyria who could add to his title, Egypt, Paturisi (biblical, "Pathros") and Kus (biblical, "Cush," "Ethiopia"). In his list of 22 tribute-paying kings of the Westland, we find "Manasseh of Judah." He was succeeded by his son, Assurbanipal (the "Sardanapalus" of the Greeks, and "Osnappar" of Ezra iv. 10). Egypt had revolted about the time of the death of Esarhaddon, and thus necessitated the early attention of Assurbanipal to hold it. He was completely successful, driving back the rebel Tirhakah, and re-establishing his authority over the whole land. A second expedition was required again in 663 B.C., when the land was completely reconquered and Assyrian authority re-established. Very soon, however, Psamtik of Egypt, with the help of foreign troops, threw off the yoke of Assyria. Assurbanipal's great work was the conquest of Babylon and his rebellious brother Shamash-shum-ukin in 647 B.C.; and, after several terrific battles, the crushing of the power of the Elamites in 640 B.C., by the capture and destruction of their great capital, Susa. These colossal military achievements marked the culmination of Assyria's career, for henceforth there was a rapid decline. Assurbanipal's notable contribution to the history of literature was his causing to be collected and copied for his royal library at Nineveh many of the most famous pieces of literature found in the libraries of Babylon. The last years of his reign are wrapped in obscurity.

Third Period — Babylonia: Rise of Babylon, 625 B. C. Fall of Assyria, 606 B. C.—Almost simultaneously with the death of Assurbanipal (626 B.C.) we find one of his former generals, Nabopolassar, a Chaldean by descent, securing the throne of Babylon for himself (625–605 B.C.). While he was developing and extending his influence and grasp over the territory that was naturally tributary to Babylon, momentous events were occurring in the north country, in and about Assyria. The growing Median power threatened its very life. Two sons of Assurbanipal, Assur-etil-ilâni and Sin-shar-ishkun, occupied the Assyrian throne, the former about four and the latter about seven years. The waves of the Umman-Manda, peoples to the north and northeast of Nineveh, were rolling over the mountains of eastern Armenia and northern Media. According to an inscription of Nabonidus, written about 553 B.C., these mountaineers finally succeeded in overwhelming Nineveh, the last hiding-place of the Assyrian tyrant and oppressor, in 606 B.C.; this was done probably with the direct or indirect support of Nabopolassar of Babylon.

Nebuchadrezzar II. 604–561 B. C.—Simultaneously with the fall of Nineveh we find an Egyptian army under Necho encamped in northern Syria, in full possession of the eastern coast of the Mediterranean Sea. In a crushing defeat Nebuchadrezzar overthrew and pursued the Egyptian invaders, and secured that territory for the new Babylonian empire. Within the 44 years of his reign, Nebuchadrezzar made Babylon the up-to-that-time greatest of empires. His authority extended, on biblical evidence, even into Egypt, and his activities were something phenomenal. In fact, the larger part of his inscriptions already found are devoted to his immense building projects, including temples, palaces, streets, embankments, and walls. Babylon was built in great magnificence, and in every important aspect did credit to the enterprise and genius of Babylonia's greatest monarch. His own records thus far found do not give us any account of his dealings with the Jews, either at Jerusalem or those in exile,— described in the Old Testament. After a long and prosperous reign he was succeeded on the throne by his son, Evil-Merodach. This king was assassinated after a reign of two years (561–560 B.C.), by Neriglissar, his brother-in-law. This usurper ruled four years (559–556 B.C.), and spent most of his time, according to his inscriptions, in building operations. At his death, his son, Labashi-Marduk, not yet of age, succeeded him, but fell under the assassin's knife within nine months.

Nabonidus, 555–538 B. C.—By some machinations of the priesthood, apparently, the new king, Nabonidus, was a native Babylonian and not a Chaldean as was the dynasty of Nabopolassar. He was an enthusiastic religionist and antiquarian. He built and rebuilt many temples in the principal cities of his kingdom. He was the discoverer, in the foundations of a temple, as already stated, of an inscription of Sargon I., which had been placed there 3,200 years before his day, making the date of said Sargon about 3750 B.C. Nabonidus' enthusiasm carried him too far, for he attempted to centralize in Babylon the religion of the kingdom. In doing this he alienated the priesthood, and even aroused their active opposition. For throughout the history of Babylonia each city had had its own patron deity, to whom its temple was dedicated and its people devoted. The images and shrines of these various divinities were collected in Babylon. This act, with others of similar offense to the priests paved the way for his downfall before a mightier power.

Cyrus, 538–529 B. C.—Cyrus, an Elamite and Persian by descent, began an active career as a conqueror in 558 B.C. He conquered successively the Medes under Astyages (550 B.C.),

Crœsus and Asia Minor (547 B.C.), and then moved against Nabonidus, who had allied himself against this new conqueror. The Babylonian army was probably under the command of Nabonidus' son, Belshazzar. Suffering a defeat at Opis, the army of Babylon later scarcely offered resistance. Cyrus marched, almost without further opposition, to the gates of the capital city. The outraged priesthood and citizens, in open defiance of their own king, flung open the gates and welcomed the new and liberal conqueror to authority over them. Cyrus restored the gods to their cities and shrines, and permitted enforced exiles to return to their native places and lands. Besides, he became one of the ardent worshippers of the gods of the land, and established himself as a liberty-loving, people-serving potentate.

The fall of Babylon before the advance of Cyrus meant the fall of Semitic sway in Babylonia, and the rise of Aryan power. The cuneiform tongue served the purpose of a language in Babylonia for long years after this revolution. In fact, throughout the Persian and Greek periods, this same language was used in Babylonia, particularly in writing contract tablets. There are some inscriptions dating from the Parthian era, due doubtless to the enthusiastic support of the priesthood of those times. Thus for nearly or quite 4,000 years the cuneiform language was the vehicle of expression for the peoples of Babylonia.

Bibliography.—The literature on Babylonia-Assyria has already become voluminous. Consequently, in a limited bibliography, only selections will be given. These will cover the following departments of study:

(1) *Explorations and Discoveries.*—These include the early works of C. J. Rich, J. E. Taylor, A. H. Layard, P. E. Botta, Felix Jones, W. K. Loftus, and J. Oppert. Since 1870 the most important works are those of Geo. Smith, H. Rassam, E. de Sarzec, John P. Peters, H. V. Hilprecht, and M. J. de Morgan, freely cited in all works on discoveries in those lands.

(2) *Inscriptions and Texts.*—Cuneiform texts began very early to be published. The first notable publication was Rawlinson's text and translation of the Behistun Inscription in the 'Journal of the Royal Asiatic Society' (Vol. X., 1847). Botta, Layard, and Oppert also published inscriptions as a result of their explorations and excavations. H. C. Rawlinson edited (1861–84) for the trustees of the British Museum five standard volumes of texts under the title 'Cuneiform Inscriptions of Western Asia.' Many minor series have appeared since that date, such as 'Assyriologische Bibliothek' (1881—), edited by Delitzsch and Haupt; 'Babylonian Expedition of the University of Pennsylvania,' by H. V. Hilprecht (1893—); 'Cuneiform Texts in the British Museum' (1896—), by officials of that museum; 'Découvertes en Chaldée' (1884—), by E. de Sarzec; eight volumes of 'Assyrian-Babylonian Letters' (1892—), by R. F. Harper, and 'Mémoires de M. J. de Morgan' at Susa, in which V. Scheil has edited notable Susian texts, and the Code of Hammurabi. In addition to these there are scores of lesser texts of value to the student.

(3) *Equipment for Study of the Language.*—The former dearth in this field has been largely supplied by Frdr. Delitzsch. His 'Assyrische Lesestücke,' 4th edition; his 'Assyrian Grammar' (1889), 'Assyrisches Wörterbuch' (1887—), and 'Assyrisches Handwörterbuch' (1896), constitute a fairly good outfit. Other works helpful in the same line are D. G. Lyon's 'Assyrian Manual' (1886), Brünnow's 'Classified List of Cuneiform Ideographs' (1889), Muss-Arnolt's 'Concise Dictionary of the Assyrian Language' (1894—); L. W. King and H. Winckler have likewise contributed liberally to this department of work.

(4) *Translations, Commentaries, etc.*—There is a long list of this material, but some of the most useful for modern students are 'Records of the Past' (1888–92), new series, edited by A. H. Sayce; 'Keilinschriftliche Bibliothek' (1889—), edited by E. Schrader; 'Assyrian and Babylonian Literature' (1901), edited by R. F. Harper; 'Zeitschrift für Assyriologie' (1886—), edited by C. Bezold; several volumes in Delitzsch and Haupt's 'Assyriologische Bibliothek,' already referred to; 'Kosmologie der Babylonier,' by P. Jensen; and several admirable series just issued by L. W. King and R. C. Thompson of the British Museum, and by C. H. W. Johns of Cambridge.

(5) *Learning, Religion, Art.*—Selections only: Fr. Lenormant, 'Le Magie chez les Chaldéens' (1874); ———, 'La divination et la science des présages chez les Chaldéens' (1875); F. Hommel, 'Die Vorsemitische Kulturen in Ægypten und Babylonien' (1883); A. H. Sayce, 'Religion of the Ancient Babylonians' (Hibbert Lectures, 1887); 'Higher Criticism and the Monuments' (1st ed. 1893, several later editions); A. Jeremias, 'Babylonische-assyrische Vorstellungen vom Leben nach dem Tode' (1887); C. P. Tiele, 'Geschichte d. ægyptische u. d. babyl.-assyr. Religion' (1895); M. Jastrow, Jr., 'Religion of Babylonia and Assyria' (1898, new revised ed., 1905, appearing in German); H. Zimmern, 'Beiträge zur Kenntniss der Babylonischen Religion' (1901); Perrot and Chipiez, 'Histoire de l'art dans l'antiquité,' Vol. II.: 'Chaldée et Assyrie' (1884); older works, such as those of Botta, Layard, and Place, are of value chiefly for their illustrations.

(6) *History and Archæology.*—Some of the most recent works superseding the large work of George Rawlinson are G. Smith, 'History of Babylonia,' edited by Sayce (1877); G. Smith, 'Assyria from the Earliest Times to the Fall of Nineveh' (1875); F. Hommel, 'Geschichte Babyloniens u. Assyriens' (1885–9); C. P. Tiele, 'Babyl.-Assyrische Geschichte' (1886–8); H. Winckler, 'Geschichte Babyl. u. Assyriens' (1892); J. F. McCurdy, 'History, Prophecy and the Monuments' (1894–1901); R. W. Rogers, 'History of Babylonia and Assyria' (1900); G. S. Goodspeed, 'History of the Babylonians and Assyrians' (1902); Schrader-Whitehouse, 'Cuneiform Inscriptions and the Old Testament' (1889); Schrader-Winckler-Zimmern, 'Die Keilinschriften und das Alte Testament' (3te auflage, 1901–3); Ira M. Price, 'The Monuments and the Old Testament' (4th ed. 1905); A. Jeremias, 'Das Alte Testament im Lichte des alten Orients' (1904).

Further bibliographical material may be found in the periodicals devoted to Assyriology, 'Zeitschrift für Assyriologie,' the 'American Journal

of Semitic Languages and Literatures,' and 'Orientalische Bibliographie'; also in the comprehensive articles on "Assyria" and "Babylonia" by Hommel and King in Hastings' 'Dictionary of the Bible,' and Cheyne's 'Encyclopædia Biblica,' respectively.

IRA MAURICE PRICE,
Professor of Semitic Languages and Literatures, The University of Chicago.

Ast, äst, **Georg Anton Friedrich,** German scholar and philosophical writer: b. Gotha 29 Dec. 1778; d. Munich 31 Oct. 1841. In 1805 he was appointed to the chair of Classical Literature at Landshut, and in 1826 accepted an appointment to the same chair in the University of Munich. Among his best known publications are: 'Handbuch der Aesthetik' (1805); 'Grundriss der Geschichte der Philosophie' (1807); 'Wissenschaftliche Darstellung der Grammatik, Hermeneutik und Kritik' (1808); 'Platos Leben und Schriften' (1816). He also published an edition of the works of Plato in eleven volumes with a Latin translation and a commentary (1810–32).

Astacus (Ital., *astaco,* Lat., *astacus,* Gr., **ἀστακός**), a genus of decapod *Crustaceans* of the family *Astacidæ,* including the *A. marinus,* or lobster, and the *A. fluviatilis,* or crayfish. The species *A. fluviatilis* contain the crayfishes of Europe, and also those of the Pacific States of the United States, while those found along the Atlantic coast belong to the species *Cambarus.*

Astarte, ȧs-tär'tē, a character in Byron's play, 'Manfred.' The hero guiltily falls in love with her, and in the second act her shadow appears to him in a denunciatory attitude.

Astar'te, a genus of bivalve mollusks belonging to the family *Cyprinidæ.* They have 2-2 hinge teeth, and are suborbicular, compressed, thick, smooth, or concentrically furrowed shells. Tate estimated the recent species known at 20 and the fossil at 285. The former belong to the Temperate and Arctic zones, and the latter to the rocks from the carboniferous formation upward.

Astarte, as-tär-te, or **Ashtoreth,** a Syrian goddess, probably identical with the *Semele* of the Greeks, and the Ashtaroth of the Hebrews, and worshipped also by the Phœnicians, and Carthaginians, being regarded by some as the original of the Greek goddess *Aphrodite* (*Venus*). She was the moon-goddess, or goddess of the heavens, and appears also to have been worshipped as the goddess of fruitfulness. In the Old Testament, Astarte is frequently mentioned as the goddess of the Sidonians (see 1 Kings xi. 5–33; 2 Kings xxiii. 13), but the form of her name seems to have been perverted, to her original name of Ashtart being infixed the vowels of Bosheth, or "shame," and we find her there called Ashtorath. In 1 Samuel xxxi. 10, Astarte is again mentioned, as is also the fact that a temple was built to her at Ashkelon. There were also temples at Citium in Cyprus, at Eryx in Sicily, and in Carthage. The Syrians also built a famous temple to her at Hierapolis, at Tyre, and at Sidon. She is probably identical with the Assyrian goddess Ishtar, or Istar, the "Lady," the "Queen of the Gods" or the virgin goddess of death and war, who enforces strict chastity upon her priests and priestesses. Astarte is represented in various forms, but more usually with four wings, the two uppermost representing the horns of the moon, and having on her head a pointed cap, and a white dove in her hand. Others represent her as a naked female figure, short and stout, and the hands holding the breasts. She is also represented in Phœnicia as a cow.

Astatic (as-tat'ĭk) **Needle** (Greek, "unstable"), in physics, a magnetic needle whose tendency to set itself in the magnetic meridian has been nearly or quite neutralized in some way, so that while the needle retains its full magnetic power, it will remain indifferently in any position, even when quite free to turn. A magnetic needle may be made astatic in various ways; for example, by disposing magnets in the vicinity of the needle in such a way that their field of force opposes and neutralizes the earth's field. A commoner method is to make use of a pair of needles of equal size and equal magnetic strength, securing them together, one above the other, by a light, rigid connection, so that their lengths shall be parallel, and their poles turned in opposite directions. If the conditions here assumed are fulfilled rigorously, the system will have no directive tendency whatever. In practice it is quite possible to secure an adjustment so good that the directive tendency is masked by the torsional force of the suspending fibre. Astatic needles are used in the construction of delicate galvanometers, the coil conveying the current passing around only one of the needles of the system, or around both of them, in opposite directions. The full magnetic moment of the current is thus obtained, while the directive action of the earth's field remains practically zero, and the motion of the needle is opposed only by the torsion of the suspension. See GALVANOMETER.

Asten, äs'tĕn, **Friedrich Emil von,** German astronomer: b. Köln 1842; d. 1878. From 1870 he was employed at the Imperial Russian Observatory at Pulkowa. He will be best remembered for his work upon Encke's comet, the results of which were published in 1877, and included an elaborate discussion of all the appearances of this interesting body from 1819 to 1875.

Aster, äs'tėr, **Ernst Ludwig von,** German military engineer: b. Dresden 5 Oct. 1778; d. Berlin 10 Feb. 1855. His first service was in the Saxon army. It was in 1810, as an officer in this army, that he submitted his plans, subsequently accepted, for the fortification of Torgau to Napoleon. Subsequently he entered the Russian service, and, soon after 1815, the Prussian. While in the last service he undertook the fortification of Coblentz and Ehrenbreitstein, and in 1842 was appointed general and inspector of all the Prussian fortresses.

As'ter, a genus of plants belonging to the natural order *Compositæ,* and comprehending several hundred species, mostly natives of North America, although some of the species are found over most regions of the globe. The name is derived from the Greek aster, a star, and is due to the fact that the flowers (*capitula*) bear some resemblance to stars. The species are herbaceous plants, or more commonly

shrubs. On account of the large number of species composing this genus it is divided into six or seven groups, regarded by some botanists as forming distinct genera. Large as the genus is, it contains no species of any great utility in the arts, but many are cultivated as ornamental plants. The most beautiful species among those which are natives of Europe are the *A. alpinus, amellus,* and *pyreneus,* and among those of America, *A. grandiflorus, punicaeus, eminens, multiflorus, horizontalis, thyrsiflorus, roseus,* and *Novæ Angliæ.* The China aster (*A. chinensis*), introduced from China upward of a hundred years ago, is a well-known annual, growing to a height of from 12 to 18 inches, and bearing an abundance of large and beautiful flowers, exhibiting in the numerous varieties every hue except yellow, and a great diversity of marking. This plant lends itself readily to culture and florists are constantly adding new varieties to a stock that already numbers nearly 300. The French call this species Reine Marguerite. Some botanists refer it to a separate genus which they call *Callistephus.* The chrysanthemum and peony flowered varieties are particularly worthy of cultivation for the size, color, and abundance of their flowers. From the lateness of the season in which they bloom some species of aster have obtained the name in England of Christmas daisy. Of the species commonly cultivated in gardens, several bloom in July, and a few continue in flower from November until killed by frost, or the beatings of violent storms.

Asterisk («a little star»), a sign or symbol (*) used in writing and printing, as a reference to a note at the bottom or on the margin of the page. The obelisk, or dagger (†), and many other marks, are similarly employed; but when there are several references on the same page, it is now common to use the numerals 1, 2, 3, etc. The asterisk often marks the omission of words or sentences, or it distinguishes words as conjectural or obscure, or it may be used merely as a typographical mark for any specified purpose.

Asterism, a property possessed by a few minerals of exhibiting star-like rays. It is due either to reflection of light from twinning lamellæ or minute enclosed tubes, as in the case of star-sapphire (q.v.), star-ruby, and star-quartz (q.v.), or to the regular arrangement of minute enclosed crystals as seen by transmitted light, in the case of some phlogopite or star-mica.

Asteroidea, an order of *echinoderms,* the starfishes, so called because of their star-like shape. They are characterized by five or more arms, which they have the power to reproduce if broken off. Should one of these arms be entirely detached, taking a small portion of the body with it, a new fish will result.

Asteroids, a group of small planetary bodies, known also as minor planets, which revolve round the sun between the orbits of Mars and Jupiter. The most remarkable feature of these bodies is that they occupy a vacant place in the solar system in which a planet would naturally belong. Between the orbit of Mars, the fourth planet in order, and that of Jupiter the fifth, there is a space more than double the radius of the orbit of Mars itself. This gap was noticed from the time that the distances of the planets were laid down by Kepler. It was long suspected that a planet would be found occupying it and an organized effort was made to discover it. The discovery of a planet which was supposed to be the long sought body was made by Piazzi, at Palermo, on the first day of the 19th century. To the great surprise of astronomers three other planets were found in the course of the next six years to be revolving in the same region. The smallness of the four bodies gave rise to the celebrated hypothesis of Olbers, that these bodies were the fragments of a single planet which had been disrupted by some cataclysm. Some 40 years elapsed when in 1846 a fifth asteroid was discovered. Others soon followed. More powerful telescopes were applied to the search, a thorough system was introduced, and in this way the number known went on increasing until it mounted into the hundreds and now a dozen or more are frequently added to the list in a single year.

When photography was applied to form a permanent picture of the stars in the sky, it was found that this method was the easiest by which discoveries of these objects could be made. Whatever method may be used, the difficulty of discovering an asteroid arises from the fact that it is impossible to distinguish such a body from a fixed star by its mere aspect. It can be detected only by its motion among the stars, and therefore requires that the same body should be observed at different times. But a photograph enables the motion to be detected in a very simple way, as follows:

If a telescope, mounted so as to serve as a camera, is pointed at a given region of the sky for half an hour or more, the images of the stars which fall on the plate remain immovable, and these bodies are photographed as simple points of light. But if an asteroid is in the field, its motion during the exposure is quite appreciable; and its picture appears as a short line, equal in length to the amount of motion during the exposure of the plate, which can be detected at sight. During the last ten years the number thus discovered has carried the total list up to more than 500, a number so great that it is almost impossible to compute the orbits or motions or even to find separate and appropriate names for the bodies.

The asteroids are distinguished from the major planets by several distinct and interesting features. One of these concerns their orbits. While the major planets, with the exception of Mercury, all move in nearly circular orbits, the orbits of the asteroids are, in the general average markedly eccentric. In some cases the asteroid is twice as far from the sun at aphelion as at perihelion. One result of this is that they appear several times brighter when seen in opposition at perihelion than at aphelion. The inclination of the orbits is also frequently very large. That of Pallas, one of the original four, is inclined no less than 34° to the elliptic. The result of this is that many of these bodies wander far outside of the limits of the Zodiac; indeed, in many cases they are seen north of the zenith in our latitudes when nearest the earth.

The size and mass of the asteroids do not admit of very accurate definition, for the reason that, with rare exceptions, they are seen in the telescopes only as points of light. Barnard, has, however, succeeded in measuring the apparent diameter of the first four, three of which are

probably the largest of the group, with the great Lick telescope. The results are:

	Miles
Diameter of Ceres	485
Diameter of Pallas	304
Diameter of Vesta	243
Diameter of Juno	118

Only the largest shows a diameter exceeding one twentieth that of the earth, and all the others are much smaller than this. Judging from the amount of light they reflect very few of them are 100 miles in diameter and most of those known may not exceed 10 or 12 miles in extent. Indeed, we have reason to believe that as we take smaller diameters the number increases without any unit. The same remark might apply in a still greater extent to the masses. The latter are so small that the attraction of the whole mass of all the asteroids does not produce any effect that has yet been observed upon any planet or comet.

Of the total number of these bodies it is hardly possible to form any estimate, because the more powerful the means of research the more are found. We can hardly be astray in supposing that thousands exist, and if we include those that must forever remain invisible to us, the number must be countless. Yet they are all so minute that the total mass cannot be as great as that of the planet Mercury.

The hypothesis already mentioned, that these bodies are fragments of a great planet, has been effectually disproved by modern research. Apart from the impossibility of an explosion which would rend a planet, we have the fact that in the event of a disruption all the orbits would pass through a single point. It is true that this coincidence would not continue indefinitely, because the orbits would change their positions by the attraction of the other planets; but their sizes are found to be such that they could not originally have passed through any single point. The view now prevalent is suggested by the nebular hypothesis, which assumes that all the planets were at some remote epoch in the past spread out into rings of matter circulating around the sun. In the case of the eight major planets each ring condensed into a single body, but in the case of the asteroid ring it separated into countless small bodies instead of condensing into one. There is a curious grouping of the orbits which seems to have some connection with the origin of the whole collection. Thirty years ago it was noticed by Kirkwood that, if the orbits were arranged according to their mean distance from the sun, there would be gaps in the series at those points where the time of revolution was commensurable with the period of Jupiter. For example, there are no known asteroids having a period one third that of Jupiter, or one half or two fifths, although there are plenty of orbits within and outside these peculiar limiting values. The subsequent discovery of hundreds of these bodies has led to a slight modification of this law. The orbits not only seem to avoid these peculiar values, but to accumulate midway between them. To get an idea of the results suppose that every orbit stretched into a circle of a radius equal to its mean distance. Then treating these orbits as hoops, suppose that we arrange them all round on one centre. We should then find that the rings are divisible into four, five or six nearly distinct groups with vacant spaces between them. The most probable explanation seems to be that there were originally five or six different rings of matter from which these bodies condensed, instead of a single ring as in the case of the larger planets.

Perhaps the most remarkable of the asteroids was one discovered in 1898. Some of its peculiarities have excited great attention on the part of the astronomical world. The orbits of all the other known asteroids are contained between the orbits of Mars and Jupiter, no known orbits approaching very near either of these planets. But, in the summer of 1898, Witt, of Berlin, found an asteroid which at perihelion came far inside the orbit of Mars, indeed within 14,000,000 miles of the orbit of the Earth. Its orbit was found to be extremely eccentric and, which was more curious, it was interlinked with that of Mars, so that if the orbits were rings, they would have passed through each other and hung together like two links. What gives this planet especial interest is that on these rare occasions when it comes nearest to the earth its parallax can be measured with greater precision than that of any of the other planets. It therefore affords us the best possible method of directly measuring the Solar system; but, most unfortunately, it is only once or twice in a century that the nearest approach will occur. What is most tantalizing, is that only six years before it was discovered, it is known to have passed at nearly the least distance from the earth, but it was then unseen by human eye. It was found to have been photographed a great number of times at the Harvard Observatory; but among the hundreds of stars whose images were found on the plate, its image was completely lost after the discovery in 1898. It was recognized through the determination of its orbit which made possible the computation of its position in the heavens at former positions. It was by scrutinizing the photographic plates that the images were found upon them.

In the winter of 1900–1 there was as close an approach to the earth as will occur during the next 30 years, although the distance was more than double the least possible distance. A cooperative effort was made to measure the parallax on this occasion. The results are not completely worked out, owing to the immense amount of labor which is required for the reduction of the observations.

A curious property of this most remarkable body is a periodical variation in its light which was noticed during the opposition of 1900–1. It was found to go through a series of changes in the course of five hours quite similar to those of a variable star. The period was found to be 2½ hours, but possibly the same brightness was not reproduced except in a period of 5 hours. It was yet more curious that these variations seemed to have nearly or quite ceased at the next opposition.

Simon Newcomb, LL.D.

Asterolepis, a genus of ganoid fishes named on account of the starry color of its scales. A bone of a species belonging to this genus, found at Stromness, the capital of Orkney, suggested to Hugh Miller the writing of his beautiful volume entitled 'Footprints of the Creator; or, the Asterolepis of Stromness.' It was an elaborate argument against the development hypothesis. According to that hypothesis, the first species of any class appearing on the scene should be low in organization, and probably small in size. Mr. Miller showed that the asterolepis was large in size and high in organ-

ization, and yet it was at that time believed to be the oldest fossil vertebrate found in Scotland. His argument was subsequently weakened by the discovery that the Stromness rocks were less ancient than the Forfarshire beds, containing cephalaspis and other fish genera subsequently discovered, mostly of small size, though not of low organization.

Asthe'nia, a disease of poultry, known in the United States as "going light." The treatment is purgation and tonics.

As'theno'pia. See EYE.

Asthma, as'ma, or az'ma, a disturbance of the function of breathing, sometimes due to heart or kidney disease, but properly an affection of the bronchi of a spasmodic character. It is regarded as a neurotic affection, characterized by turgor and hyperemia of the mucous membranes of the smaller bronchi and a peculiar mucus exudate. The causes of the attacks are many, but a nervous element seems to enter into most of them. The symptoms are those of tightness in the chest, depression, and followed by an attack of shortness of breath, attended with violent coughing. This may be very short in duration or the coughing may continue with great violence. The expression is anxious, the face pale, or cyanosed, as though choking was taking place; the patient cannot speak, inspiration does not aerate the blood, and expiration is long and wheezy. The treatment is individual, the usual lines of dietetics, hygiene, training, with a few drugs. Iodide of potash is one of the most valuable of the remedies used. See 'Diseases of the Bronchi, Nothnagel's System' (1902).

Astig'matism, a defect of vision in which the rays of light do not converge to a single point on the retina. It is usually due to irregularities in the curvature of either the cornea or the crystalline lens, or of both, so that rays refracted in one meridian are brought to a focus at a point in advance of or behind those refracted in the meridian at right angles to the first. A slight degree of astigmatism is present in all eyes, because neither the cornea nor the anterior or posterior lens surface is part of a perfect sphere: but normally the defect is so slight as not to be noticeable. The conventional star-shaped appearance assumed by very distant points of light, as, for example, the stars themselves, is due to this universal defect. If, however, the radii of curvature are markedly unequal in the different meridians, a more or less serious blurring of the images formed on the retina by all objects results. Two main varieties of astigmatism are recognized. The commoner is *regular* astigmatism, in which there is a difference of curvature in two meridians, usually at right angles to each other, but the refraction is the same throughout any given meridian. In *irregular* astigmatism, however, there are variations of curvature along the length of the different meridians themselves; that is, each one does not, as in regular astigmatism, represent a segment of a circle. This form is usually the result of injury or disease of the cornea or lens, and is difficult to correct by glasses. Regular astigmatism is nearly always congenital and is frequently present in several members of the same family. The symptoms produced by astigmatism may be purely local and comprise blurred vision and fatigue after protracted near work, but even slight amounts may in some cases cause serious disturbances of the general health by the constant headache and reflex symptoms, such as nausea and vomiting, dizziness, etc., that result. The difficulties complained of are usually, at least partly, relieved by resting the eyes. Numerous methods of examination are employed by oculists to detect astigmatism, one of the simplest being the use of test diagrams representing radiating lines or sectors, rows of dots, etc., which, to the astigmatic eye, appear more or less blurred in certain meridians. The treatment consists in the use of glasses which are ground so as to compensate for the variations in refracting power of the optic media in the different meridians. This correction is accomplished by using cylindrical lenses, which are segments of cylinders and refract only at right angles to their axis, combined, if necessary, with the appropriate spherical lenses. See EYE; VISION, DEFECTS OF.

As'ton, William George, Irish philologist: b. near Londonderry in 1841. He became interpreter and translator to the British Legation at Yedo, in 1870; assistant Japanese secretary at Yedo, in 1875–82; consul-general for Korea, in 1884; Japanese secretary at Tokio, in 1886; and was retired in 1889. He published 'A Grammar of the Japanese Spoken Language'; 'A Grammar of the Japanese Written Language'; 'A Translation of the Nihongi; or, Annals of Ancient Japan'; 'History of Japanese Literature,' etc.

As'tor, John Jacob, American merchant: b. Waldorf, Baden, near Heidelberg, 17 July 1763; d. 29 March 1848. He came to America in 1783, where his elder brother had settled and invested his savings in the fur trade. In 1784 he went with a cargo of furs to London; sold them and formed connection with fur houses there, and as his capital increased, made annual trips to Montreal, buying furs there and shipping them direct to London, as Canada was allowed to trade only with the mother country. In 1794 Jay's treaty removed this embargo; and Astor, then in London, at once made a contract with the Northwest Company of Montreal and Quebec (then the magnate of the Canadian Northwest fur trade), imported furs from Montreal to New York, and shipped them to all parts of Europe and China. The surrender of the lake posts under the treaty also greatly extended the trading limits, and Astor in a few years became one of the leading merchants and capitalists of the country, having a quarter of a million in 1798, and double that a few years later. In 1807 he embarked in direct trade with the Indians by way of the Mohawk, and with the English fur companies; but found the American trade chiefly monopolized by the Mackinaw Company, and knowing our government's desire to keep its home trade in home hands, proposed with its protection to accomplish this himself. In 1809 he secured a New York charter for the "American Fur Company," but the War of 1812 suspended operations, and after it a government prohibition of British fur trade in the United States broke up the company. Meantime a grander scheme had been initiated. Sir Alexander Mackenzie, after crossing the Continent far north in 1793, had suggested establishing a line of trading posts from ocean to

ocean, with terminal, coast, and island stations, to draw all except the Russian fur trade into one channel. Lewis and Clarke's transcontinental American expedition in 1804 proved its practicability on American soil; and Mr. Astor evolved the plan of distributing such posts along the Missouri and Columbia Rivers, with a central station at the mouth of the latter, where all the peltries from the interior posts and those gathered by coasting vessels were to be collected, and taken by a yearly ship to Canton, loading in return with Chinese goods. A later development was to operate a line of ships from the Pacific coast to the Chinese and East Indian ports, with a Hawaiian island for an intermediate port. The Russian fur company had already complained to the United States of the casual American trading vessels selling liquor and firearms to their Indians; our government had consulted Astor for a remedy, and his idea was to abolish this irresponsible trading by making his yearly supply ship take its place. To prevent ruinous competition, he offered the Northwest Company a one third interest in the enterprise; but they declined it, and sent a company to seize the mouth of the Columbia before his party could arrive. He succeeded in spite of them, however, in planting a settlement, which was named Astoria; but on the breaking out of the War of 1812 the English seized it. It reverted to the United States by the Treaty of Ghent, and Astor wished to revive the project, but the government was cool, and he dropped it; still, however, buying his furs direct and trading with many countries, more particularly China, at that time the best fur mart in the world. He also made large amounts by buying depreciated government securities, which afterward commanded a considerable premium. But his chief investment was the one which has founded the family greatness on a rock. Foreseeing the immense growth of New York city, he bought large tracts on Manhattan Island far beyond the then city limits, taught his son to invest his accumulations in the same way, and established the system of handling them described under ASTOR FAMILY. In 1827 he and his son William, who had been his partner since 1815, withdrew from the China trade and formed the American Fur Company, chiefly managed by the great expert; but a few years later he retired from business altogether, thenceforth devoting himself to his investments, and devising, in consultation with others, plans for a public library suggested by Washington Irving, — afterward the Astor Library, for which he left $400,000 in his will. He made gifts and bequests to other objects; among them $50,000 for a school for poor children and a home for the indigent aged in his birthplace, Waldorf, called the Astor House. He was much more than a great trader: he had a breadth of conception, a combined energy and patience of execution, a mastery of detail, a retentiveness of memory, and a sagacity of judgment, which in the judgment of his intimates would have raised him to greatness in any line. He left two sons, William B. and John Jacob, and three daughters.

As'tor, John Jacob, an American capitalist and soldier, son of William B.: b. New York, 10 June 1822; d. 22 Feb. 1800. He was educated at Columbia University and at Gottingen; he then took the full course at the Harvard Law School, and practised law for a year, solely to qualify himself for assisting in the management of the immense estate, one half of which later descended to him. In the Civil War he served on McClellan's staff, with the rank of colonel; and was a devoted and hard-working military student. He always regarded this period as the best of his life, and attended the reunions of the Loyal Legion with zeal. Not only was he always a liberal giver to public institutions and charities, but he gave much personal time and devotion to them, especially to the Astor Library and Trinity Church; but he shrank from public notice. On his father's death in 1875 he received half of the estate, estimated at considerably over $100,000,000; all which, with accumulations believed to have swollen it to some $200,000,000, he left to his only son, William Waldorf Astor. His wife, Charlotte Augusta Gibbs, was an active assistant in his charitable work, taking part in personal service as "Sister Augusta," incognito.

As'tor, John Jacob, American capitalist and inventor, fourth of the name, nephew of John Jacob the third, and son of William: b. Rhinebeck, N. Y., 13 July 1864. He graduated from Harvard in 1888, and for the next three years traveled abroad. He is the manager of the Astor properties in America; a director in many banking, insurance, and railroad companies, and member of various clubs and social organizations. He built in 1897 a very costly hotel, the Astoria (named after the famous fur settlement of 1811), on Fifth Avenue, New York, adjoining the Waldorf built by his cousin, William Waldorf, the two being now joined as the Waldorf-Astoria. Besides his business activities, however, he has strong individual faculties. He is an expert in marine mechanics. inventor of a bicycle brake, and a pneumatic road improver; and is a member of scientific and other intellectual societies. He has written 'A Journey in Other Worlds: a Romance of the Future' (1894). He was on Gov. Morton's staff 1894–6, and in the Spanish-American war of 1898, was commissioned lieutenant-colonel of United States Volunteers, and served in the Santiago campaign.

Astor, William Backhouse, American merchant and capitalist, eldest son of John Jacob Astor: b. New York, 19 Sept. 1792: d. 24 Nov. 1875. He was trained in his father's business in the intervals of public school education: and the father is said to have remarked that "William would never *make* money, but would keep what he had." At 16 he was sent to Heidelberg University, and at 18 went to Gottingen, where he was tutored by Bunsen, afterward the great chevalier. Returning to New York in 1815, he was made a partner in his father's foreign shipping trade, especially cultivating the Chinese field. The firm was John Jacob Astor & Son till 1827, when it dissolved and both partners gave up the China trade to form the American Fur Company, of which William was president, but John Jacob the head manager till he withdrew from active business life a few years later. He was shortly followed into retirement by his son. By 1848 he had amassed a fortune of his own; besides receiving a legacy of half a million from his uncle Henry, and a gift of the Astor House

from his father; the latter on his death in that year leaving him sole legatee save for minor bequests, the property being estimated at $20,000,000 to $30,000,000. His life thenceforth was spent in conserving and developing this. He built nearly a thousand houses on his uptown lots, and was currently termed "the landlord of New York." He was also a heavy investor in other lines, notably coal and railroad stocks. He founded the Astor Library under his father's bequest, adding by gifts and bequests over $600,000 to his father's gift, giving much time to its administration from the completion of the building in 1853 on his plans. His wife was the daughter of Madison's second secretary of war; his sons were John Jacob and William, and the estate was shared between them.

Astor, William Waldorf, an American capitalist, son of John Jacob the third: b. New York, 31 March 1848. He is the head of the chief Astor estate. He was educated by private tutors; studied law to qualify himself for the management of his estates, and assumed it in 1871. He was elected to the New York State lower legislative chamber in 1877, and to its Senate in 1879; and was an unsuccessful candidate for Congress in 1881. In 1882 he was appointed minister to Italy by President Arthur, and remained such till 1 March 1885. He made literary capital out of this in 'Valentino' (1885) and 'Sforza' (1889). He succeeded by his father's death in 1890 to a fortune estimated at some $200,000,000, and the same year removed to London. Shortly afterward he built the famous and costly New York hotels, the New Netherland and the Waldorf. In 1893 he bought the 'Pall Mall Gazette' and founded the 'Pall Mall Magazine,' and in 1899 took the oath of allegiance as an English subject.

As'tor Family, a famous American family representing one of the three or four greatest private properties in the world. A family in the Old World sense,— a territorial aristocracy, impossible to destroy, and fortified with legal immunities and privileges,— can hardly be founded in America; but the Astors have approached it as nearly as our institutions will admit. They form a group of immense hereditary real-estate owners, with holdings so solidly based and well distributed in the metropolis of America that no apparent catastrophe save a failure of heirs could extinguish it; and though originally springing from mercantile business, removed by some three quarters of a century from its actual conduct. For many years they were known as "the landlords of New York," and the best of landlords, prompt, just, and courteous; still probably form the largest set of individual real-estate holders. The family is also connected with notable municipal charities and public foundations. See Astor, John Jacob (1763–1848); Astor, John Jacob (1822–90); Astor, John Jacob (1864–); Astor, William.

Astor Library. See New York Public Library.

Astor Place Riot, in American history: a riot on the evening of 10 May 1849, in Astor Place, New York. It was an attempt to drive the English actor, William Charles Macready (q.v.) from the stage, and grew out of a London tour of Edwin Forrest (q.v.), in which he played Virginius and Richelieu with great success till Macready bought the acting rights for himself, though he had personally treated Forrest with kindness. Forrest then essayed Macbeth, but it was unsuited to his style and presence, and he was hissed. He attributed this to Macready's machinations, and when Macready four years later announced 'Macbeth' in the Astor Place Opera House, a crowd of Forrest's partisans gathered early in the evening before the theatre, and waiting till the performance had begun, attempted to force a way inside and put a stop to it. The police were powerless and sent for the military; the Seventh Regiment (New York militia) came up, and was assailed by the mob with showers of brickbats and stones. Before the fray was ended, 34 rioters were killed, a great number wounded, and 141 of the regiment injured by the missiles. The mob was successful in its purpose, however: Macready had to cancel his engagement, conceal himself in a private house for a couple of days, and then travel secretly to Boston, whence he sailed for England. See Barrett, 'Edwin Forrest' (1882).

Astor'ga, Emanuele d', an Italian composer: b. Palermo, 11 Dec. 1681; d. 21 Aug. 1736. He was educated in a monastery in Astorga in Spain, from which he afterward took his name. A 'Stabat Mater,' which he is said to have written in London, is considered the best of his works, and is still highly regarded.

Astorga, as-tōr'ga, a city in Spain, the *Asturica Augusta* of the Romans. It figured prominently during the Peninsular war; was taken by the French after an obstinate defense, 1810; and retaken by the Spaniards, 1812. It is the see of a bishop. Pop. 5,000.

Astoria, Or., a city, port of entry, and seat of Clatsop County: on the Columbia River, nine miles from its mouth, and 101 miles by the Astoria & C. R. R.R. from Portland. Several foreign steamship lines touch here, the largest vessels coming up to its five miles of water frontage through the deep, broad channel scoured in the bar at the river mouth by a jetty. Its salmon fishing and canning industries are among the greatest in the world: several hundred boats go out to the fishing grounds on the bar every afternoon during the season of about 100 days, some 1,500 in all being employed; and the canneries utilize some $2,000,000 capital, and turn out about 15,000,000 cans a year. It has also subsidiary can manufactories and iron works, great lumber works from the vast forests of the Pacific slope, flouring mills, breweries, etc.; and has a very large export trade in the special products of Oregon and Washington — lumber, wheat, oats, live stock, wool, potatoes, apples, etc. Among its buildings, the most notable are the United States custom-house, the post-office, and St. Mary's Hospital (R. C.). For the founding of Astoria in 1811, see Astor, John Jacob. On its seizure by the English in the War of 1812, they renamed it Fort St. George; in 1818 it was restored to the United States, though occupied till 1845 by the fur stations first of the Northwest Company, then of the Hudson Bay Company with which the former consolidated. It received a city charter in 1876. Pop. (1900) 8,381.

Asto'ria, or Anecdotes of an Enterprise Beyond the Rocky Mountains, a rambling

work by Washington Irving (1836). It comprises stories of expeditions by land and sea, and as a chapter of Far West history, does not lose its value by the lapse of time.

Astrabad, äs'tra-bäd', a town of Persia, about 30 miles east of the Caspian Sea. It carries on a trade in horses, sheep, cotton, silk, woolen fabrics, etc., and is connected by caravan with Afghanistan and is the seat of a Russian consulate. Pop. estimated at from 4,000 to 10,000.

Astræ'a, in mythology, the daughter of Zeus and Themis, and goddess of justice. In the age of gold she was a regular inhabitant of this world; in the age of silver an occasional visitor; and in the age of brass, when men began to forge weapons of war, fled to the skies, where she is seen in the zodiac, forming the constellation Virgo. She is usually represented with scales in her hand and a crown of stars on her head.

Astræ, The Divine, a name applied to the English novelist and dramatist, Mrs. Aphra Behre, who was noted for the coarseness of her plays. "The stage how loosely doth Astræa tread."

As'tragal, in architecture, a small semicircular molding, with a fillet beneath it, encircling a column and separating the shaft from the capital.

As'tragaloman'cy (Greek *astragalos,* in the plural = dice, and *manteia* = divination), a pretended divination performed by casting down dice with marks corresponding to letters of the alphabet, and observing words thus formed. It was practised in the temple of Hercules, in Achaia.

Astragalus. See Foot.

Astrag'alus, Milk Vetch, a genus of more than 1,000 species of hardy leguminous herbs and under shrubs which, except in Australia where they have not been found, are of world-wide distribution on dry soils. *A. gummifer* and other species yield tragacanth (q.v.) gum. Certain species native to the western United States called crazy weeds (q.v.) are considered responsible for crazy disease of stock. The leaves are usually pinnate; the flowers arranged in racemes, white or purple. A few native and foreign species are grown from seed for ornamental purposes. They succeed best on dry, porous soil in sunny situations.

Astrakhan, äs'trakhän', a government in the southeast of European Russia, on the Caspian; with an area of about 92,000 square miles. It consists almost entirely of two vast steppes, separated from each other by the Volga, and forming for the most part arid sterile deserts. The live stock consist chiefly of sheep of the broad-tailed species. The chief employments are pasturage and fishing — the former occupying the rural and nomadic tribes, and the latter the tribes on the Caspian coast and the banks of the Volga. Pop. (1897) 994,775.

As'trakhan', the capital of the Russian government of the same name. It is situated on an elevated island in the Volga, about 30 miles above its mouth, and consists of crooked, dirty, but broad streets, with irregular lines of houses. The communication with the opposite banks of the river is maintained by numerous bridges. The most important edifice is the cathedral, of a rectangular form, with four small gilt and painted cupolas on the roof, and a large one in the centre. The manufactures, consisting of silks, cottons, woolens, shagreen skins, morocco leather, and soap, are increasing in extent. The fisheries furnish the staple articles of trade. Immense quantities of fish, caviar, and isinglass are exported to foreign countries. In the fishing season from 20,000 to 30,000 persons connected with the fisheries frequent the city. It is the naval station of the Caspian fleet; is the most important port of the Caspian, and has regular steam communication with the principal towns on the shores of that sea. Pop. (1897) 113,001.

As'trakhan', a name given to sheep-skins with a curled wooly surface obtained from a variety of sheep found in Bokhara, Persia, and Syria, and also to a rough fabric with a pile in imitation of this.

As'tral Spir'its, spirits believed by the Greeks and Orientals to inhabit the heavenly bodies or the aërial regions. In the Middle Ages they were variously conceived as fallen angels, souls of departed men, or spirits originating in fire, and belonging neither to heaven, earth, nor hell. Paracelsus regarded them as demoniacal in character.

As'trapothe'rium, an extinct hoofed animal found in the Miocene formations of Patagonia. It is unlike any modern animal, but is distantly related to the extinct Toxodonts of South America. It was as large as a rhinoceros, had large tusks opposing each other in the upper and lower jaws, and a broad flexible muzzle like that of the hippopotamus, or possibly a short proboscis like that of the tapir.

Astringents. Substances that have the property of precipitating albumin and other proteids act as astringents. When used on mucous membranes they contract the tissues, diminish the blood supply, decrease the mucus and modify the sense perceptions in the part. In the mouth they cause the well-known sensation of puckering. Their action is purely local. Vegetable astringents all contain tannic acid, to which substance their action is due. Nearly all of the mineral salts are astringent when used well diluted with water. In concentrated solution their coagulant action is so pronounced as to cause death of the tissue (caustic). The astringents are particularly serviceable in stimulating atomic mucous membranes, causing them to secrete less mucus. They are thus useful in chronic diarrhœas, in leucorrhœa and in mucous discharges from other parts of the body. The most serviceable of the vegetable astringents is tannic acid, or its compounds, tannalbin, tannigen, and related bodies. Of the mineral salts, solutions of copper sulphate, zinc sulphate, lead acetate and the aluminum salts are the most useful.

As'tro-photog'raphy. It seems likely that attempts to photograph the moon were made by Daguerre in the course of the experiments which led to the first successful method for making optical images permanent. Certainly in 1840 Draper, of New York, obtained a crude and imperfect picture of the moon, after a prolonged exposure of the Daguerreotype silver plate. In 1851, and the years immediately following, the collodion wet-plate process was introduced and

developed. By this method De la Rue, Draper, and Rutherford were enabled to produce pleasing photographs of the moon. Much advance was made, during the same period, in the application of photography to other celestial objects, but it cannot be said that the results, on the whole, were other than interesting and suggestive. Obviously, however, the work was full of promise of better things, and the modern developments along this line afford an impressive illustration of the growth of a scientific toy into a potent instrument of research. In the early seventies the gelatine dry-plate became generally available, and from that time astronomical photography has steadily grown in effectiveness and applicability. In outline, astronomical photography is like any other photography. By means of a suitable lens an optical image of whatever is to be photographed is thrown upon the sensitive plate. It is immaterial whether the object be a landscape, the moon, an animal, or a constellation. After an exposure whose duration is determined by experience, the plate is removed and "developed" by any of the well-known processes. The result is a reproduction, in light and shade, of the optical image. From this plate, called a "negative," may be made prints, transparencies, etc. The obstacles met with, however, in carrying out this apparently simple process when applied to celestial objects, are many and great. On account of the rotation of the earth, the heavenly bodies are seemingly in motion from east to west. Some of them, moreover, have sensible motions of their own. Thus it is necessary to provide compensating motions for the camera or photographic telescope so that the image shall remain in the same place on the plate during exposure. This is a mechanical problem of great difficulty. Again, the camera must be used from the bottom of a deep atmospheric ocean turbid with smoke, dust, ice-crystals, and vapors, and swirling with currents and eddies. This obstacle is the most serious one in all astronomical work. It becomes more and more disastrous as the magnifying power of instruments is increased, and is but imperfectly overcome by careful selections of sites for observatories, and of times for work when the air is relatively quiet. There are many other difficulties which attend the processes of practrical astronomical photography, but these two are fundamental. On the other hand, there are at least two fundamental advantages in the photographic method as compared with the direct visual method of studying the sky. When measurements are to be made — such as, for example, the measurement of the angular distance between two neighboring stars — the direct method often calls for careful, accurate work under trying conditions. The observer may be hurried, in a constrained attitude, or shivering with cold. Checks by a second observer may be of doubtful value on account of personal equation or changed conditions. If, however, the two stars be photographed on the same plate, the measurements may be made at leisure, in physical comfort, and with every precaution for insuring accuracy. In the second place, the effect of light-vibrations upon the sensitive substance of the photographic plate is cumulative. That is the longer the plate is exposed the greater the effect of the light upon it. (There is, no doubt, a maximum, but it lies outside the range of photography.) Upon the retina of the human eye, however, or upon the optic nerve, there is no such cumulative result. We gain nothing by looking for a long time toward an object whose light is too feeble to affect the sense of vision. When, after a while, we see an object not previously discerned, it is because the attention is directed to it, not because the retina is more affected.

It is on account of this property of the photographic plate that prolonged exposures have revealed faint objects or peculiarities of structure, not visible to the keenest eyes aided by the most powerful telescopes. As an important though subsidiary advantage of the photograph, may be mentioned the possibility of presenting to the sight enlarged representations of relatively extensive celestial areas. The field of vision of a great telescope is very small. A photograph of a nebula or of a star-cluster, projected by a fine lantern, at once exhibits a convincing general view, revealing things in structure and arrangement which might long escape the notice of one studying the object with a telescope. The difference is much the same as that between a broad view of a landscape and the same examined through a long tube of small diameter. Photography is at present employed in almost every line of astronomical research. The general divisions of the subject are, however, indicated in what follows.

Star Charts.— By agreement among the authorities of some score of observatories in different parts of the world, there has been undertaken the enterprise of photographing the entire heavens. The plates are of uniform size, and the lenses used are as nearly as possible identical in figure. One set of photographs is to include stars down to the eleventh magnitude, while a second set is to include everything that can be secured by the longest practicable exposure. The value of the resulting charts to the astronomy of the future can scarcely be overestimated. Had such a map been constructed a few centuries ago it would now throw great light on problems relating to the structure of the universe. Meantime the study of the photographs already secured has been of importance in modifying theories as to the distribution of the stars, in revealing asteroids, new stars (so called), and variable stars.

Photographs for Detail.— Up to the present time the greatest success in this line of endeavor has been attained in photographing the moon, the sun, and nebulæ. The superb lunar photographs produced at the Lick Observatory and at the Observatory in Paris leave little to be desired, although they are inferior to the best views obtained by the direct use of the telescope. These wonderful pictures cannot fail to be of great future value in showing to what extent, if at all, changes take place on the surface of our satellite. The photographs of the sun are, thus far, somewhat less satisfactory as to minute details. The air between the observer and the sun is almost constantly disturbed, and it is not easy to take advantage of instants of "good seeing" for securing the pictures. Nevertheless the accumulations of solar photographs, taken as they are every day, constitute a most admirable history of what goes on in the sun's surface and help toward a correct understanding of solar physics. At recent total solar eclipses many

thousands of photographs of the corona have been secured. These naturally differ widely in scientific value, but it must be admitted that the best of them fall short of revealing all that is seen by the eye. The "fogging" of the plates from the light in the atmosphere in the solar direction obscures the image of the outer corona. The eye recognizes this faint extension rather by its tint than by its luminosity as compared with that of the sky. Photographs of the nebulæ, on the other hand, taken by prolonged exposures on moonless nights, have greatly advanced our knowledge of the structure of these objects, and have led to modifications in the statement of the nebular hypothesis. Photographs of the planets have thus far failed to give satisfactory results in exhibiting surface markings.

Photographs for Measurement.— Aside from the construction of star-charts as described above, the photographic method is used in an increasing number of cases in which the most accurate angular measurements are desired, and is now fairly comparable with the heliometer method. Among the more important applications of the new process is the determination of parallax by photographing Mars when near the eastern horizon and again when near setting; the rotation of the earth, meantime, having carried the observer from one end to the other of a base-line whose length depends upon the latitude of the station and the time between the exposures. Precisely the same method was applid to the newly discovered asteroid Eros during the latter part of the year 1900. It is clear that the difference in place of the planet among the stars, when the eastward picture is compared with the westward, is due to parallax, allowance being made for the movements of the planet and the earth during the interval between the observations. A similar method may be used in investigations of stellar parallax, the photographs being taken at half-yearly intervals, thus securing a base-line nearly or quite equal to the diameter of the earth's orbit. Photographs of stellar spectra afford a means for detecting and measuring the motion of stars in the line of sight by noting the displacement of the lines toward either end of the spectrum. Through investigations of this sort it has come to be believed that there are many large, dark stars associated with visible stars, constituting, in some cases, systems of great complexity. The existence of such a dark body is inferred from the alternate approach and retreat of the visible star, relatively to the earth, this motion being apparently due to a revolution of the bright star about, or with, an invisible companion. In some cases, also, the periodic duplication of the spectral lines seems to indicate that a star is double, both components giving out light, while the largest telescopes fail to resolve the pair to the vision.

Photometry.— With a given time of exposure the size and blackness of the stellar images are proportioned to the brightness of the stars. This fact renders it easy to prepare lists of stars in order of brightness or "magnitude." The method is the less valuable, however, for the reason that the color of a star influences the chemical effect of its light upon the plate. A bright red star gives a smaller image in a given time than a fainter white or blue star. A complete photometric classification of the stars should be based upon measurements of the intensity of several portions of their spectra.

Transits, etc., by Photography.— By mechanical means it has been sought to eliminate the personal equation by photographing a star and the reticle of a transit or similar instrument at intervals automatically measured and recorded by clockwork. This must be taken as a very general statement of a method which, in a variety of forms, may yet be developed to a high degree of usefulness.

Instruments for Astronomical Photography. — It is well known that the lens of a visual telescope is quite unfit for photographic work. Those portions or components of white light that are best for seeing are not the components most effective in producing the negative. The blue and violet rays, left outstanding in the chromatic correction of the ordinary telescope, are precisely the ones wanted in photography, and they confuse and spoil the negative when the visual lens is tried as a photographic lens. Hence there must be a special objective for use in photographing, or an auxiliary lens for transforming the visual objective for its new work. So-called "portrait" lenses are much in use when a short focus, with large field and small images, is required. Lately much progress has been made in the use of mono-chromatic plates covered by colored glass screens, for absorbing the light that is not wanted. In this way it is possible to do good work in certain lines without a special lens. The accurate pointing of the telescope or camera is a matter of extreme difficulty, especially during long exposures. No driving clock yet produced, even when controlled, through electric devices, by the standard timepiece, is quite satisfactory. Therefore, it is necessary, in very many cases, that two telescopes, one visual and one photographic, should be bound together, and that an observer should keep the pair accurately pointed by hand. This is a most delicate operation, calling for great power of concentration, and for special deftness of touch. The observer, with eye at the visual telescope, keeps the cross-hairs of the eyepiece precisely upon a selected star. He watches and modifies the rate of the driving clock, moves the telescope as atmospheric refraction varies, and seeks in general to prevent all motion of the image on the plate. Upon the successful accomplishment of this difficult undertaking depends the final value of the photograph. In certain classes of work, however, the stars are allowed to "trail" a little, so that their images may readily be distinguished from specks and imperfections in the plate. The "coudé" telescope is much favored in Europe for photography, on account of the great steadiness of the eye-end and the comfort afforded the operator. In this country, when long-focus lenses are to be used, the tendency is toward the fixed horizontal telescope, a detached siderostat reflecting the light from the object into the telescope.

Among the more important adjuncts in instrumental devices should be mentioned the beautiful machines for measuring distances on the photographic negatives, this apparatus taking the place of the micrometer eyepieces used for direct measurements with the telescope.

F. S. LUTHER.

As'trocar'yum, a genus of about thirty species of tropical American pinnate-leaved palms noted for their profuse sharp spines sometimes a foot long. *A. murumuru,* the murumuru palm, a common species in the lower Amazon region, seldom attains a height of more than 20 feet. It bears an edible, melon-flavored, musky-scented ovate fruit about an inch long, the pulp of which is highly prized as food for man and cattle. Hogs crush the seeds, which are almost as hard as vegetable ivory, and fatten well upon them. *A. tecuma,* the tecuma palm, reaches a height of 30 to 40 feet, and has very regularly arranged spines, bears an edible, globular fruit, and is native of the same region as the preceding species. *A. vulgare* is a taller-growing palm than the above. The unexpanded leaves furnish a strong fibre, for which the tree is often cultivated where it is not native. To obtain this fibre the terminal bud is cut and the epidermis of the delicate leaves carefully peeled in ribbon-like strips that when dry are twisted into fine, strong durable threads used for making twine, bowstrings, hammocks, fish-nets, etc. The fibre of older leaves is coarser, tougher, and stronger, and is used for cordage; the petioles of the young leaves are used for making into baskets and hats. This species, commonly known as the tecum palm, is distinct from the tecuma palm noted above, but was confounded with it by Maritius, who pictured the tecuma as the fibre-bearing species. Consult: Wallace, 'Palm Trees of the Amazon' (1853). Several species are cultivated in greenhouses for ornamental purposes and specimens as large as 10 feet tall often bear fruit. For culture, consult: Bailey and Miller, 'Cyclopedia of American Horticulture' (1900–2).

As'trolabe (from Greek *astron*, a star, and *lambano,* I take), the name given by the Greeks to any circular instrument having one or more graduated circles. In modern astronomy this instrument is no longer used, because wholly superseded by the sextant. The first application of the astrolabe to navigation was made by the physicians, Roderich and Joseph and Martin Behaim of Nürnberg, when John II., king of Portugal, desired them to invent a method of preserving a certain course at sea. Angles of altitude were found by suspending the astrolabe perpendicularly.

Astrology, the science which pretends to foretell future events, especially the fate of men, from the position of the stars. Originally, that is, among the Greeks and Romans, the word had the meaning of «astronomy,» and, as in the case of alchemy and chemistry, the pseudo-science and the real science had the same origin. In early times, when the earth was regarded as the centre of the universe and as that to which all else was somehow tributary, it was a not unnatural hypothesis that the changing configurations of the heavenly bodies might be indicative of human destiny, or might influence human character. Hence, the Chinese, the Egyptians, the Chaldæans, the Romans, and most other ancient nations, with the honorable exception of the Greeks, became implicit believers in astrology. It was partly the cause and partly the effect of the prevalent worship of the heavenly bodies. The «star-gazers,» sarcastically referred to in Isa. xlvii. 13, were perhaps astrologers; so also may have been what are called in the margin «viewers of the heavens»; but the Hebrew word rendered «astrologers» in Dan. i. 20; ii. 2, 27; iv. 7; v. 7, is a much vaguer one, meaning those who practise incantations, without indicating what the character of these incantations may be. The later Jews, the Arabs, with other Mohammedan races, and the Christians in mediæval Europe were all great cultivators of astrology. Some of the greatest astronomers, among whom was John Kepler, who knew very much better, were accustomed to «cast horoscopes,» and to receive large fees for so doing. The ordinary method of procedure in the Middle Ages was to divide a globe or a planisphere into 12 portions by circles running from Pole to Pole, like those which now mark meridians of longitude. Each of the 12 spaces or intervals between these circles was called a «house» of heaven. The sun, the moon, and the stars all pass once in 24 hours through the portion of heavens represented by the 12 «houses.» Every house has one of the heavenly bodies ruling over it as its lord.

The houses symbolize different advantages or disadvantages. The first is the house of life; the second, of riches; the third, of brethren; the fourth, of parents; the fifth, of children; the sixth, of health; the seventh, of marriage; the eighth, of death; the ninth, of religion; the tenth, of dignities; the eleventh, of friends; and the twelfth, of enemies. The houses vary in strength, the first one, that containing the part of the heavens about to rise, being the most powerful of all; it is called the ascendant, while the point of the ecliptic just rising is termed the horoscope. The important matter was to ascertain what house and star was in the ascendant at the moment of a person's birth, from which it was deemed possible to augur his fortune. It followed that all people born in the same part of the world at the same time ought to have had the same future, an allegation which experience decisively contradicted. Even apart from this, astrological predictions of all kinds had a fatal tendency to pass away without being fulfilled; and when, finally, it was discovered that the earth was not the centre of the universe, but only a planet revolving around another body, and itself much exceeded in size by several of its compeers, every scientific mind in Europe felt itself unable any longer to believe in astrology, which has been in an increasingly languishing state since the middle of the 17th century. It still flourishes, however, in Asia and Africa, and is a means of livelihood to many charlatans who prey upon the ignorant classes in all countries.

As'tronom'ical and As'trophysi'cal Soci'ety of America, a national society whose members must possess technical knowledge of astronomical and astrophysical science. Membership (1903) 180.

Astronomy. Astronomy is that branch of science which treats of the heavenly bodies — including practically all the bodies of the universe. The great advance which our times have witnessed in the methods of research has made it one of the most progressive of the sciences, while it is, at the same time, the oldest of all. The vast extent of its field, including the entire universe within its bounds, leads to its having

a number of different branches. There is, first, a branch which embraces our general knowledge of the heavenly bodies, their motions, aspects, and physical constitution. This branch is commonly termed descriptive or general astronomy. It is now recognized as having two divisions, one relating principally to the motions, mutual relations, and general aspects of the heavenly bodies; the other to their physical constitution, considered individually. The former division is sometimes termed astrometry, because it is principally concerned with measurements of position, motion, mass, etc. The other branch is termed astrophysics, and is that which has received its greatest development in recent times. There is also a branch which teaches the methods of observing the heavenly bodies, including the instruments used in observation and measurement, and the principles governing their use, as well as the practical computations incident thereto. This branch is termed practical astronomy. Another branch is the mathematical one, which determines the orbits and motions of the heavenly bodies by deductive methods, taking as a basis the facts of observation and the laws of motion, especially that of gravitation. This branch treats of the orbits of the heavenly bodies and of the methods of computing the effects of their mutual attraction. It is commonly termed theoretical astronomy, while the more purely mathematical theory is known as celestial mechanics.

The subject of astronomy is treated in the present work on the following plan: We begin with a brief but comprehensive survey of the universe, referring to special articles — Stars, Universe, Nebulæ, Solar System, etc., for details. This survey will be followed by reviews of Practical Astronomy, Theoretical Astronomy, and of the historical development of the science.

Descriptive Astronomy.— Considered as to their nature, the heavenly bodies may be divided into two great classes; the one, incandescent bodies which shine by their own light; the other, opaque bodies which are visible only by reflecting the light of some incandescent body in their neighborhood. Examples of the first class are the stars which stud the heavens at night; examples of the second are the planets, of which our earth is one. From the very nature of the case, little can be learned of the possible number of opaque bodies which may exist in the universe. There may be some rather uncertain ground for inferring that they are less massive and less numerous than the incandescent bodies; but it is sometimes supposed that they may far outnumber the latter without our being aware of the fact. The stars are scattered through the wilderness of space at distances which baffle all our powers of conception. Light moves with such speed that it would make the circuit of the earth seven times in a single second. But the cases are rather exceptional when a star is so near one of its neighbors that light would not take years to travel over the distance which separates them. Indeed, the only known exceptions belong to the class of double or multiple stars — two or more such bodies forming a system by themselves. There is only one star so near us that its light would reach us in four years, and the same is probably true of most other stars. That the universe of stars extends to distances which light would require several thousand years to travel is certain; but no well-defined limit has yet been set to its extent. Our sun is one of the stars, and is the one of which we know most because of our proximity to it. It is the centre around which eight great planets and a number of other bodies perform their revolutions. On one of these great planets, the third in the order of distance, we dwell. Our knowledge of the heavens is largely conditioned by our residence on this planet. We see the other planets by the light of the sun, which they reflect. They present to the naked eye the appearance of stars; and it is only when scrutinized with the telescope that they are found to have a measurable apparent size. Vast indeed is their distance from the sun when measured by our standards. Yet, the dimensions of our solar system are very small when compared with the distance which separates the stars. Light passes from the sun to the outer planet, Neptune, in about four hours, while, as we have said, it requires years to reach any star. The nearest star is therefore thousands of times farther than the most distant planet. A most interesting question is whether other stars have systems of planets revolving round them, as our sun has. This is a question which it is impossible to answer conclusively. Planets revolving round the stars would be absolutely invisible through the most powerful telescope that man can ever hope to construct. In special cases, however, evidence on the subject is afforded by the spectroscope, which shows that great numbers of stars really have one or more dark bodies revolving around them. But, in order to be observable with the spectroscope, these bodies must be vastly larger than the planets which revolve round our sun. The existence of a planet like that on which we dwell could not be determined even with the best spectroscope.

The bodies of the solar system are bound together by the law of gravitation. Were it not for the attraction of the sun each planet would fly off in a straight line through space. Through the attraction of the sun all the planets are kept in their several orbits. Every consideration leads us to believe that gravitation extends from one star to all the others, but diminishing as the inverse square of the distance. But its effect on bodies so distant as the stars is too minute to be observed. Revolving double stars, however, show that in these exceptional cases, systems of two stars in proximity to each other are subject to the law of mutual attraction.

The three fundamental facts which determine the great phenomena of astronomy, as we observe them in the course of our lives are (1) the globular form of the earth on which we dwell; (2) its diurnal rotation on its axis; (3) its annual revolution round the sun. The first of these facts is so familiar to all that we need not discuss it. Out of it grow the general phenomena of the sky. The heavenly bodies surround us in every direction. They are really as numerous by day as by night, only in the former case they are blotted out by the brightness of the sky. To imagine the heavens as they really are we must fancy stars as always visible in every part of the sky. Then, by day, we should see the sun among the stars, and perhaps the moon also. Mere observation

of a heavenly body gives us no idea of its distance. By looking at a star we cannot tell whether its distance is to be measured by hundreds of miles, by millions, or by thousands of millions, which it actually is. Hence, all the heavenly bodies appear to us to be at the same distance, as if they were set upon the interior surface of a stupendous sphere in the centre of which we seem to be placed. This imaginary form is called the celestial sphere; it is one of the most ancient conceptions of astronomy, and it is used in the science to the present day to represent the appearance of the heavens. It is divided into two hemispheres, a visible and an invisible one. The visible hemisphere is the half which is above the horizon, which we call the sky and can always see, except so far as obstructions or inequalities of the ground may prevent. The other half is below the horizon, and is hidden from our view because the earth is opaque. Were the latter transparent, we should see the heavenly bodies in every possible direction. The revolution of the earth on its axis produces the phenomena of day and night, and the apparent rising and setting of the heavenly bodies. This is known as the diurnal motion. The latter may be considered in two aspects, either as the real revolution of the earth on its axis, in a direction always toward the East, or as an apparent revolution of the heavens in the opposite direction, due to our being unconscious of the motion of the earth. In consequence of the diurnal motion the celestial sphere, seeming to our eyes to carry the heavenly bodies on its interior surface, appears to us to make a daily revolution on its axis. The two opposite points of the celestial sphere situated on the prolongation of the earth's axis are called the celestial poles. On these poles as pivots the celestial sphere seems to turn. They are called north or south according to the direction. Their apparent position in the sky depends on the latitude of the place where the observer is situated. A heavenly body situated at either pole does not seem to have any diurnal motion. This is nearly the case with the pole star, which dwellers north of the equator can always see at an altitude above the northern horizon equal to their latitude. A voyager into the southern hemisphere sees the pole star set when he crosses the equator. Then, the south polar star would be visible if there were one. But it happens there is no bright star very near the southern prolongation of the axis. In the United States, say from 30° to 45° of latitude, the pole star is at a corresponding altitude above the horizon, and all the stars in its neighborhood appear to make a diurnal rotation round it, without changing their form or position, and without ever setting. Any one who chooses can verify this fact by noting the appearance of the northern sky about the end of twilight, and then looking at it again two or three hours later. He will then see that stars below the pole have moved toward the east; those on the east side of it have risen higher, and those on the west side are lower, while those above have moved over toward the west. For us, therefore, the sphere of the heavens may be divided into three parts; a circle round the north celestial pole within which stars never set; a corresponding circle round the south pole, the stars in which never rise above our horizon, and a broad middle region where they rise and set.

To represent the positions of the stars, astronomers imagine circles on the celestial sphere corresponding to the circles of longitude and latitude on the earth. As we imagine north and south meridians drawn on the earth from one pole to another, to measure terrestrial longitudes, so we imagine in the heavens circles drawn on the sphere from the north celestial pole to the south one. As the longitude of a place on the earth is expressed by the angle which its meridian makes with the meridian of Greenwich, so the corresponding quantity for a star is the angle which the circle through it makes with a certain prime meridian on the celestial sphere. This quantity for the stars is not called longitude, but *right ascension,* and the celestial meridians which determine it may be called *hour circles.*

In the same way as we have on the earth a great circle spanning it, everywhere equally distant from the two poles, and called the equator, so we imagine a circle spanning the heavens, everywhere equally distant from the north and south celestial poles, which is called the celestial equator, or the equinoctial. At any one place this circle will be apparently fixed in its position, always intersecting the horizon at its east and west points, and, in our latitudes, intersecting the meridian south of the zenith by a distance equal to our distance from the equator. For example, to a dweller in latitude 40°, the highest point of the celestial equator will be 40° from the zenith, and 50° above the horizon. From this point it spreads toward the east and west until it intersects the horizon as just stated. As a traveler journeys south, the position of the celestial equator becomes more and more nearly vertical; at the equator it rises vertically and passes through the zenith; south of the equator it passes north of the zenith.

As the latitude of a place is measured by its angular distance from the equator north or south, so the corresponding number for a star is measured by its mean angular distance from the celestial equator, whether north or south. This is called the star's *declination.* Thus the right ascension and declination of a star determines its position on the celestial sphere just as longitude and latitude determine the position of a city on the earth.

We now have to consider the effect of the annual motion of the earth round the sun. If we watch the heavens at a certain hour every evening, say eight o'clock P.M., we shall find that the stars are every night a little farther advanced in their diurnal motion then they were the night before. If they are in a certain position at eight o'clock on one evening, they will pass the same position four minutes before eight on the next night, eight minutes before eight on the next night, and so on. In the course of a year these continually accumulating changes make up the whole 24 hours, so that a star which is in the zenith this evening will be on the meridian at eight o'clock in the morning six months hence, while at eight in the evening it will be at its greatest distance below the horizon. If we could see the sun among the stars, what we should notice would be that our luminary always forges a little

farther east day after day, and in the course of a year seems to make a complete revolution among the stars. The result is that while the sun rises and sets 365 times, the stars rise and set 366 times. Since the latter are always in the same absolute direction, and seem to rise and set in consequence of the earth's rotation on its axis, we infer that the direction of the sun from the earth goes through a complete revolution in the course of a year. In other words, the sun appears to us to make an annual revolution around the celestial sphere among the stars. Since the time of Copernicus it has been known that this appearance is due to the actual revolution of the earth around the sun.

The apparent path of the sun among the stars can be mapped out by astronomical observation. When carefully observed, it is found to be a great circle of the sphere, called the ecliptic. We thus have two imaginary circles of fundamental importance spanning the heavens. One is the celestial equator, the other the ecliptic in which the sun seems to travel. These circles do not coincide, but intersect each other at two opposite points at an angle of 23½°. This is called the *obliquity of the ecliptic*. The result of it is that during one half the year the sun is south of the celestial equator, and during the other half is north of it. In the northern half of its course we have summer in the northern hemisphere and winter in the southern; in the southern half we have summer in the southern hemisphere and winter in the northern. Thus the changing seasons are due to the obliquity of the ecliptic. If the latter coincided with the equator, we should have no such annual round of seasons as that with which we are familiar.

There are two opposite points on the celestial sphere at which the equator and the ecliptic intersect. These are called *equinoxes* because, when the sun crosses them, the days and nights are equal all over the earth. That equinox which the sun passes toward the north is called the vernal equinox, because the crossing marks spring in the northern hemisphere. The other is called the autumnal equinox for a similar reason. Observations continued through many centuries show that the equinoxes are not fixed, but travel slowly along the ecliptic at such a rate that they make a complete revolution from the east toward the west in about 26,000 years. This motion is called the precession of the equinoxes. Its existence shows that the direction of the earth's axis is slowly changing, and hence the position of the celestial pole is changing also. Since the equator is defined by the condition that it spans the heavens midway between the celestial poles, this change in the poles causes a corresponding change in the equator.

The actual motion of the pole is at the rate of about 20″ per year. The smallest visible object that can be seen to be anything else than a point of light subtends an angle of about 1′ or 60″. It follows that the pole moves through this smallest visible space in three years. In a long life of 90 years the change would be about equal to the diameter of the sun or moon. The centre of the motion is the pole of the ecliptic which is distant from that of the equator by about 23½°. Owing to the smallness of the obliquity, the equinox travels along the ecliptic at more than twice the rate of the pole, or about 50″ per year. It has therefore changed about 30° since its motion was first noticed, about 2,000 years ago. It is found that the planets describe their course around the sphere in circles which do not deviate greatly from the ecliptic. A belt of the heavens extending 11° on each side of the ecliptic will include all the planets visible to the naked eye. This belt is called the zodiac. Beginning at the vernal equinox it is divided into 12 portions, of 30° each, known as the signs of the zodiac. In former times great stress was laid upon the entrance of the sun into these several signs, which entrances occurred about a month apart. They now occur about the 20th of every month. In our times, when the superstitions connected with this subject have vanished, the entrance of the sun into the signs is no longer of importance. (See ZODIAC.) There are also 12 constellations, beginning with Aries, and ending with Pisces, which have the same names as the signs of the zodiac, and are scattered along its course. Two thousand years ago these constellations coincided pretty closely with the signs. But now, in consequence of the precession of the equinoxes, the two no longer correspond. The sign Aries is now located in the constellation Pisces; the sign Taurus in the constellation Aries, etc.

The Time of Day.— It is in its relations to times and seasons that the results of astronomical science come into every household. Our daily round of activity and rest is determined by the earth's rotation on its axis, alternatingly bringing us under the sun, and then carrying us around until it is hidden from our sight. A century ago people used to set their clocks at 12 when the sun crossed the meridian. This moment, being the middle of the day, is noon properly so-called. But if a good clock is exactly regulated, and kept going all the time, it will not show noon at the true time. The reason is that the intervals of time between one noon and the next are not exactly the same. See TIME.

Bibliography.— The most extended general treatise on astronomy for the use of the general reader is 'Chambers' Astronomy' (3 vols., 8 vo., London); briefer is Newcomb's 'Astronomy for Everybody'; Ball, 'Story of the Heavens'; Flammarion, 'Popular Astronomy'; etc.

SIMON NEWCOMB, LL.D.,
Washington, D. C.

Astronomy, History of. We may recognize four great periods in the history of astronomical knowledge. The first and most ancient is that in which no accurate observations were made, but in which men had a general knowledge of the apparent annual revolution of the sun, of the constellations, and of the relation of the sun's annual course to the changes of the seasons. The next period was that of the celebrated Alexandrian school, so-called because Alexandria was the principal seat of its activity. This period was distinguished as that at which the first attempts were made at precise observation and measurement. It began three or four centuries before Christ. It is very remarkable that, at so early a period as this, men to whom all our modern science was completely unknown, had so far advanced in astronomical observation as to measure the obliquity of the ecliptic, determine the times of the equinoxes, and detect their precession. The latter was done by a comparison of two meth-

ods of determining the length of the year, as measured by the sun's apparent revolution around the celestial sphere. Timocharis, who flourished about 300 B.C., determined the moment at which the sun crossed the equinox by means of an east and west line on the level sandy plains of Egypt, showing exactly where the sun rose or set. The day on which the point of settting in the west was exactly opposite that of its rising in the east marked the equinox, which could thus be determined within a few hours. The annual course of the sun can also be determined by the time which it takes to return to the same position among the stars after an annual apparent revolution. As the stars and sun cannot be seen at the same time, the adopted plan was to measure the distance of the sun from the moon before sunset, and after dark to measure the distance from the moon to some bright star. Allowing for the motion of the moon during the interval, the distance of the sun from the star would be known. In this way the curious discovery was made that the year as determined from the equinoxes was several minutes shorter than that determined from the stars. This discovery was made by Hipparchus through a comparison of his observations with those of Timocharis about 150 years before.

Erastothenes, who flourished just before Timocharis, was enabled to estimate the size of the earth. This he did by noting that at the ancient town of Syene, in central Egypt, the sun was exactly in the zenith at the time of the summer solstice, so that it illuminated the bottom of a well, while at Alexandria it was 1/50 of a circumference south of the zenith. He therefore concluded that the circumference of the earth was 50 times the distance between Alexandria and Syene. The latter being 50,000 stadia, it followed that the circumference of the earth was 250,000 stadia.

Hipparchus was considered as the greatest astronomer of antiquity. He made more accurate observations than any of his predecessors upon the courses of the sun, moon, and planets, determining their times of revolution with extraordinary exactness. Unfortunately none of his works survive, and our knowledge of them is derived mainly from Ptolemy's 'Almagest.'

Ptolemaic System.—Ptolemy (130–150 A.D.), besides being a practical astronomer, was accomplished as a musician, a geographer, and a mathematician. His most important discovery in astronomy was the evection of the moon. He also was the first to point out the effect of refraction. He was the founder of the false system known by his name, and which was universally accepted as the true theory of the universe until the researches of Copernicus exploded it. The Ptolemaic system placed the earth, immovable, in the centre of the universe, making the entire heavens revolve round it in the course of 24 hours. The work by which he is best known, however, is the collection and systematic arrangement of the ancient observations in his great work, the 'Megale Syntaxis,' which gives a complete *résumé* of the astronomical knowledge of the day. This work was translated into Arabic in the first part of the 9th century and was called by the Arabs the «Almagest,» and by this name it is known today in its various translations into Greek and Latin. The most important part of it is the seventh and eighth books, which contain the catalogue of stars which bears Ptolemy's name, though it is only a compilation of the catalogue of Hipparchus with the positions brought up to the time of Ptolemy. The advance of astronomy almost ceased, after the death of Ptolemy, and his 'Almagest,' together with the false system of the universe which it taught, continued to be the recognized authority in Europe for the next 14 centuries.

With the death of Ptolemy, everything in the way of actual progress in astronomical theory appeared to cease. The Arabians continued astronomical observations from time to time, and made or proposed many improvements in the ancient astronomical instruments, but they slavishly followed the system of Ptolemy, and made no attempts to penetrate the mystery of the celestial motions. They had little capacity for speculation, and throughout held the Greek theories in superstitious reverence. The most illustrious of the Arabian school were Albategnus, or Al Batani (880 A.D.), who discovered the motion of the solar apogee, and who was also the first to make use of sines and versed sines instead of chords; and Ibn-Junis (1000 A.D.), an excellent mathematician, who made observations of great importance on eclipses of the sun and moon and the motions of Jupiter and Saturn, and who was the first to use cotangents and secants. Likewise, at about the same time, Abul Wefa discovered the third inequality in the moon's motion, the variation, and determined its amount. About four centuries later, in the first half of the 15th century, lived Ulugh Beigh, a Tartar prince, who made important additions to astronomical knowledge.

The third period commenced when Copernicus, in 1543, first demonstrated the true theory of the universe to his fellow men in his great work 'De Revolutionibus Orbium Cœlestium,' His two fundamental principles were that, instead of the diurnal motion of the heavens being real, it was only apparent, being due to the revolution of the earth on its own axis; and that the apparent revolution of the sun around the sky was, in the same way, due to the actual revolution of the earth around the sun, which latter remained at rest. Centuries of observation have shown that these two principles explain so exactly every detail of celestial phenomena that they are subject to no more doubt than our conclusions as to the arrangement of streets and houses in a city which we see every day of our lives. Half a century after the death of Copernicus flourished Galileo and Kepler, of whom the first invented the telescope, while the second demonstrated the correctness of the Copernican theory, and also showed that the planet Mars revolved around the sun in an ellipse with the sun in its focus.

The invention of the telescope added another proof to the Copernican theory, and also enlarged our views of the universe by showing that Jupiter and his satellites formed a miniature solar system on the Copernican plan; that the planet Venus had phases like the moon; that the moon itself had a variegated surface apparently similar to that of our globe, and that the wonderful Milky Way was composed of innumerable stars too faint to be seen sep-

arately by the naked eye. The spots on the sun were also discovered, and the rotation of our central luminary on its axis made known. Such enormous advances were too great for the human mind at once to grasp, and the generation in which Galileo lived had to pass away before the Copernican theory was universally accepted by the learned world. To this same period belong the observations of Tycho Brahe on the motions of the sun, moon, and planets, which were, most unfortunately, made just before the invention of the telescope, and so failed of the precision which would have been gained by the use of that instrument. But, as it was, they were the basis on which Kepler founded his celebrated laws of planetary motion.

The fourth and last period began when Newton showed that all the complicated phenomena of the celestial motions — the revolution of the planets in elliptic orbits, and the revolution of the satellites around their primaries, were all due to the mutual gravitation of these bodies, and took place according to the same laws which govern the motion of matter around us on the earth. As in the case of the Copernican theory, it took the learned world a whole generation to grasp the idea of Newton as to the theory of gravitation. The progress made in our knowledge of the celestial motions during the two centuries since Newton's time have all rested on the principle which he discovered.

Toward the end of the 18th century, Sir William Herschel, then in the zenith of his fame, was interesting the whole world by his wonderful discoveries. With his great reflectors he made a step forward in the size and power of the telescope greater than any before or since. Although his greatest and best instrument would be considered extremely imperfect at the present time, those which it superseded were hardly more than what we should now call spy glasses. Herschel was so far the greatest figure of the time in astronomical science, and his work so overshadowed that of his contemporaries on the continent, that the work of everyone else at the time seems unimportant in comparison. Yet not only were great successors of Herschel coming on the stage, but important additions to our knowledge of the heavens were being made outside of England. William Herschel's son, John, was a lad of eight years. In France, Arago, a boy of 14, was fitting himself for the École Polytechnique. At Paris, Lalande, the leading astronomer of France, was actively preparing a catalogue of the fainter stars with an instrument which would now be consigned to the junkshop. But it was the first attempt that had ever been made to determine accurately the positions of the many thousand telescopic stars invisible to the naked eye, and in consequence the 'Histoire Céleste' is still one of the classics of the astronomical investigator. In Germany, Olbers combined the professions of physician and astronomer, and Bessel, a youth of 16, was clerk in a mercantile house.

The first day of the century was marked by a discovery of capital interest and importance. The wide gap between the planets Mars and Jupiter had been a source of wonder, and the conviction that there must be a planet in it had become so strong that an association of astronomers was formed to search for it. But, on 1 Jan. 1801, before they got to work, Piazzi, the Italian astronomer of Palermo, found Ceres. The year following Olbers discovered Pallas, and propounded his celebrated theory that the newly formed bodies were fragments of a shattered planet, more of which might be found. This anticipation was amply justified by the result, though the theory of a shattered planet has long been rejected. By 1868 the number reached 100. When the sky was systematically watched 100 more were found. When the process of photographing the stars was perfected, so many new ones were found on the photographic plates that it is almost impossible to follow them up. About 450 have had their orbits mapped out. See ASTEROIDS.

In this country, David Rittenhouse, almost the only American of Revolutionary times who has a place in scientific history, had been dead four years when the century began, and there was no one to take his place. He was one of the committee of the American Philosophical Society that made an extensive and well-planned set of observations on the transit of Venus in 1769. The first American after the Revolution to acquire eminence in any department of astronomical science was Nathaniel Bowditch. A Boston ship-captain by profession, he first prepared his 'Navigator,' the standard work of the sailor through most of the century. He mastered the great work of Laplace, and made it accessible to students by a translation and commentary explaining the processes in detail. So far as practical astronomy was concerned, it might be regarded as non-existent among us during at least the first third of the century. We know little more of it than that Robert Treat Paine, grandson of the signer of the Declaration of Independence, used to compute eclipses and publish the results in the 'American Almanac,' and the Boston *Advertiser*. About 1840, Dr. Lardner paid a visit to this country and remained several years, delivering public lectures, which, though not of a high order when measured by the standard of to-day, were much above any which Americans had then heard.

During the first half of the century, the advance of astronomical science consisted principally in a form of development which goes on without any striking discovery, and has therefore little interest for the general public. When bright comets appeared they were carefully studied by observers, at the head of whom were Bessel and Olbers. It was thus found that the tail of a comet was not an appendage carried along with it, like the tail of an animal, but merely a stream of vapor arising from it and repelled by a force residing in the sun. The discovery of telescopic comets by observers, here and there, continually added to the number of these bodies known. Most of them were found to be moving in such orbits that they would require thousands of years, perhaps tens of thousands, to return to the sun, if, indeed, they ever reappeared. But this, though the general rule, is far from being universal. From time to time comets were found moving in closed orbits and performing their revolution in periods of a few years, mostly between 3 years and 10.

One of the noteworthy discoveries of the third quarter of the century was that of the

relation between comets and shooting stars. The first discovery of this relation came about in a curious way. The researches of H. A. Newton and others had made it quite clear that shooting stars were due to the impact of countless minute bodies revolving around the sun in various orbits and now and then encountering our atmosphere. It was also known that the great November meteoric showers must be due to a stream of such bodies. One astronomer computed the orbit of the November meteors; and another quite independently published the orbit of a comet which appeared in 1866. A third astronomer, Schiaparelli, noticed that the two orbits were practically the same. The conclusion was obvious. The minute bodies which caused the shower moved in the path of the comet and were portions of its substance which had from time to time separated from it. The disappointing failure of the shower in 1899 and 1900 can have but one cause — a small change in the orbit of the meteoric swarm caused by the attraction of the planets. Nor has the comet associated with them shown itself; it was perhaps dissipated like that of Biela's. Apart from this, the question of the constitution of comets is still an unsolved mystery. Their spectrum is that of a body which shines by its own light. But no one can explain how a body in the cold and vacuous celestial spaces can so shine. The brighter comets may have a more or less massive nucleus. Yet it is not certain that the nucleus is entirely opaque. In 1882, the astronomers at the Cape of Good Hope enjoyed an opportunity which no one of their brethren ever enjoyed before or since; that of seeing a comet enter on the disk of the sun. Unfortunately, the sun disappeared from view a very few minutes afterward. But not a trace of the comet could be seen on the sun as a spot. It was seemingly quite transparent to the solar rays. That the fainter comets have no nucleus and are merely composed of a collection of foggy particles seems certain. How are these particles kept together through so many revotions? This question has not yet been satisfactorily answered. See Comet.

The Greenwich Observatory was taken in charge by Airy in 1834. He immediately instituted a great improvement in its organization and work, but it was not till 1850 that he acquired for it new instruments of great importance. He was the founder of what has sometimes been called the Greenwich system: the astronomers of an institution taking a part like those of soldiers in an army, making all their observations on a plan prescribed by the authority and rarely using their own discretion in any way. The mathematical theory of the motions of the planets, and especially the moon, received its greatest improvement from the hands of Hensen, born about 1795. He may fairly rank as the greatest of celestial mechanicians since the time of Laplace. Toward the middle of the century, he prepared the first tables of the moon which could satisfy the requirements of modern astronomic theory. These were published by the British government in 1857, and have now formed the basis of astronomical ephemerides for nearly half a century. The most striking event of the mid-century period, and one which in the popular mind must long hold its place as among the greatest of intellectual achievements, was the computation by Leverrier of the position of an unknown planet from its attraction on Uranus. The speedy discovery of the planet on the very night it was first looked for was, for the public, a proof of the absolute correctness of gravitational theories that surpassed all others. It was as a first and bold attempt to sail into an unknown sea; yet, as in the case of Columbus and the Atlantic, its repetition would not now be generally considered a difficult matter. With the discovery of Neptune and with the advance in the art of astronomical observation, improvements in the theories of the movements of the planets were necessary. The greatest step forward in this direction was taken by Leverrier. Among the results of his work was the discovery that the perihelion of Mercury moves more rapidly than it should under the influence of gravitation. This excess of movement has been abundantly proved by observation since his time, but its cause is still one of the greatest mysteries of gravitational astronomy. As a general rule, it may be said that during the last half century the Germans have been the leaders in astronomical research. Their work on the subject has been more voluminous than that of any other nation. The leading astronomical journal of the world is still that of Germany. But when we consider not quantity of work, but the special importance of particular works, precedence has, from one point of view, passed to America. While, perhaps, we still have fewer students pursuing astronomy in the United States than in Germany, the number of men among us who have acquired the highest distinction and most skilfully made applications of this science is greater than in any other country. The rapidity of progress from small beginnings is very remarkable.

In 1832, Professor Airy delivered, before the British Association for the Advancement of Science, an address on the progress of astronomy, which soon acquired celebrity. The state of astronomy in different countries was reviewed. America was dismissed with the remark that he was not aware of any observatory existing in that country. In the revival of astronomy among us and its advance to its present position in popular favor, one agency has not been esteemed so highly as it deserves. Contemporaneous with the visit of Dr. Lardner were the lectures of Prof. Ormsby M. Mitchel. With unsurpassed eloquence he explained the wonders of astronomy to audiences intensely interested in the novelties of the subject. From a scientific point of view the lectures were probably not of a high order, nor could it be said that Mitchel himself, active and enthusiastic though he was, was a profound astronomer. Yet it may well be said that to him is due the ability of our astronomers since that time to secure the public support necessary to the erection of the fabric of their science. A few years after Airy's address small college observatories were founded at Williams College and at the Western Reserve College, Ohio. These were doubtless a stimulus to students, but can hardly have added to astronomical science. When the Wilkes Exploring Expedition was being organized, it was found necessary to have a continuous series of observations made at home during the absence of the expedition which, compared with those made on the ships, would en-

able the navigators to determine the longitudes of the lands they discovered. A little wooden structure, erected by Captain Gilliss for this purpose, on Capitol Hill, Washington city, was in some sort the beginning of our National Observatory. The actual foundation of the latter was almost contemporaneous with that of the Harvard Observatory, both being commenced about the year 1843. The Harvard Observatory was placed under the direction of William C. Bond, who had, for many years, made observations, first at his own house in Dorchester, and then on top of a house at Cambridge. At Washington the Naval Observatory was placed under the charge of Lieut. Maury. After getting its instruments in operation, he devoted himself almost entirely to those researches on ocean currents, which, so long as the commerce of the world was carried on mostly in sailing vessels, were of the first importance. But the institution soon acquired astronomical celebrity in other ways. Here Sears Cook Walker made the first thorough investigation of the orbit of Leverrier's newly discovered planet, and showed that it had been twice observed by Lalande as far back as 1795, but without its character being suspected. Here also the device of recording the transits of stars by means of the chronograph and determining the longitude of places by telegraph found their first application. New observatories, some founded in connection with colleges, others by private individuals, now sprang up rapidly among us in every quarter. Twenty-four were enumerated by Loomis in 1856. What figure the number has now reached it is impossible to say. Whatever it may be, it marks rather the interest taken by the intelligent public in astronomical science than the actual progress of knowledge. The number of these institutions which have actually made important contributions to astronomical knowledge is naturally very small. It is to a few leading ones that most of the progress is due.

Two of these have put almost a new face upon astronomical science. These are the Harvard Observatory at Cambridge and the Lick Observatory of California. The former, while a respectable institution from its foundation, and made famous by the works of the Bonds, had never commanded the means necessary to prosecute astronomical research on a large scale. When Pickering assumed the directorship in 1875, he devoted his energies to those branches of research which are now known under the general term of astro-physics, being concerned with the physical constitutions of the heavenly bodies rather than with their motions. The extension of his work was made possible by very large additions to the endowment of the observatory. It thus became one of the best-supported institutions of the kind in the world. Photometry and spectroscopy have been its main subjects. With the aid of a branch established in Arequipa, Peru, the magnitudes of all the stars in the heavens visible to the naked eyes, as well as many fainter ones, have been determined. Among its remarkable discoveries have been those of new stars. It was formerly known that at long intervals, sometimes more than a century, sometimes less, stars apparently new blazed out in the sky. Really the star was not new, but was an old and very small one of which the light was temporarily multiplied hundreds of thousands of times. A system of constantly photographing the heavens showed that such objects appear every few years, only they do not generally attain such brilliancy as to be noticed by the unassisted eye. The success of the Lick Observatory in a different, yet not wholly dissimilar, direction must be regarded as one of the most extraordinary developments of our time. Commencing work about the beginning of 1888, under the direction of Holden, and supplied with the greatest telescope that human art had then produced, the observations of Burnham and Barnard excited universal interest, both among astronomers and the public. The discovery of a fifth satellite of Jupiter, perhaps the most difficult object in the heavens, was made there by Barnard in 1892. Later, the optical discovery of the companion of Procyon, an object known to exist from its attraction on that star, was made by Schaeberle. But its most epoch-making work is due in still more recent years to Campbell, by measurements of the motion of stars in the line of sight with the spectroscope. The possibility of measuring such motions was first demonstrated by Huggins, some thirty years ago, and was applied both by him and by the observers at Greenwich. Then a great step forward was made by photographing the spectrum instead of depending on visible observation. This step was mostly developed by Vogel, at the Potsdam Observatory, near Berlin. In the case of the variable star, Algol, Vogel was thus enabled to show that the fading away of its light at regular intervals of something less than three days was really a partial eclipse of the star by a dark body revolving around it. He also showed that three other bright stars varied in their motions to and from the earth in a way that could arise only from the revolution of massive but invisible bodies around them. Now, at the Lick Observatory, Campbell, armed with the best spectrograph that human art could make, the gift of D. O. Mills, has, by the introduction of every refinement of his method, brought into these measures a degree of precision never before reached. The cases of variable motion, as found by him, are so numerous as to indicate that isolated stars may be the exception rather than the rule. It is true that up to the present time he detects variation in only about one star out of thirteen which he observes. But it is only in the exceptional cases, where the planet is almost as massive as the star itself, that the motion can be detected. It is not at all unlikely that, for every spectroscopic binary system (as these pairs of objects are now called) we can detect, quite a number may exist in which the revolving planet is too small to affect the motion of the star. With the beginning of a new century, astronomy, the oldest of the sciences, seems to be entering upon a new career, with a prospect of a life before it the end of which no man can foresee.

SIMON NEWCOMB, LL.D.,
Washington, D. C.

Astronomy, Practical. The instruments of observation used by the working astronomer are made up mainly of various combinations

of three appliances. These are the telescope, the graduated circle, and the clock. (For the principles of the first see TELESCOPE.) With the clock is associated the chronograph as part of a combination for measuring time. Many auxiliary appliances are also brought into use of which the micrometer and the spirit level are the most important. The usefulness of the telescope in measurement does not arise solely from its enabling the observer to see objects

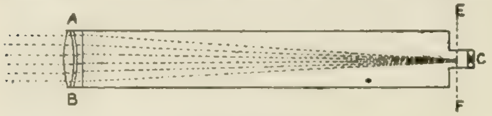

FIG. 1.

otherwise invisible. A telescope with no magnifying power at all would still enable him to determine the directions of the heavenly bodies at any moment with greater accuracy than would otherwise be attainable. The principle on which the telescope is used in celestial measurement will first be explained. Let Fig. 1 represent the section of a telescope; A B being the object glass, and C the eye-end, where the rays from a star are brought to a focus. The lines converging to the plane E F represent the rays of light from a star reaching the focus. Here they form an image of the star, which the observer sees by looking into the eye-piece at C. The plane, of which the dotted line E F is a section, passing through the focus at right angles to the telescope, is called the focal plane. By changing slightly the direction in which the telescope is pointed, the rays may come to a focus on any point in this plane not too far from the axis or central line of the telescope. In the focal plane is placed a system of very fine threads which the observer sees when he looks into the eye-piece. These threads are generally made of fibres of spider-web, a substance so well adapted to this purpose that nothing better has yet come into use. To fix the ideas we shall suppose several cross threads; then the observer by looking into the telescope may see the stars and the

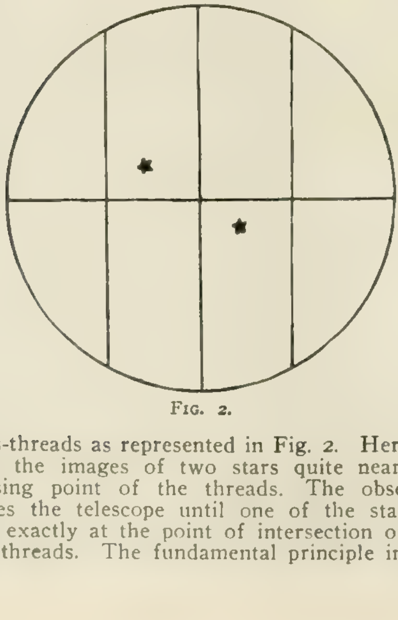

FIG. 2.

cross-threads as represented in Fig. 2. Here we have the images of two stars quite near the crossing point of the threads. The observer moves the telescope until one of the stars is seen exactly at the point of intersection of the two threads. The fundamental principle in the use of the telescope is that when this occurs, the star is apparently situated exactly on a straight line passing through the cross threads, and the centre of the object glass. This line is called the line of sight of the telescope.

Now, let the observer move the telescope until he finds another star, whose image he brings upon the cross threads. The angle through which he has moved the telescope from one star to the other, supposing the two stars to be at rest, will then be precisely the angle between the rays of light coming from the two stars. If, then, any system is adopted of determining through how many degrees, minutes,

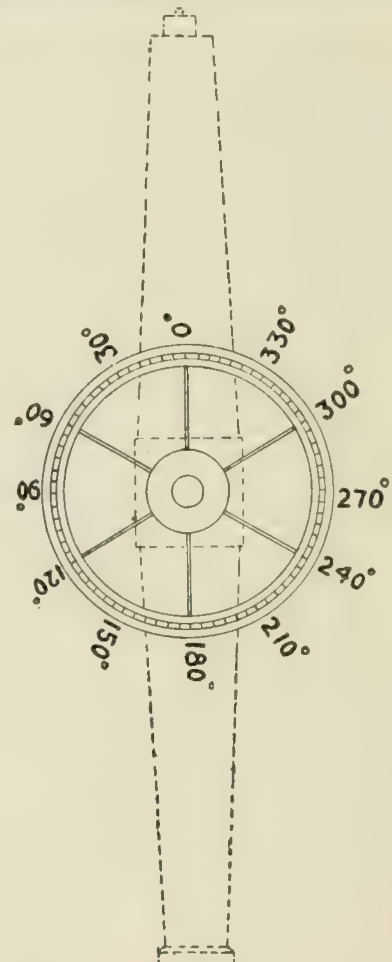

FIG. 3.

etc., the telescope has moved, the angular distance between the stars is known. The studious reader will remark that, owing to the rotation of the earth, the image of a star seen in a fixed telescope is continually moving across the field of view. To explain the principle we must, however, leave this motion out of account, or suppose it allowed for.

We have next to show how a large angle through which the telescope may be moved is measured. This is done by means of the graduated circle, a representation of which is shown in Fig. 3. It will be seen that the rim of the

circle is divided up into degrees by fine lines as represented in the figure, where, however, only every fifth degree is marked. In the instruments actually used in astronomy, not only is every degree marked, but in the circles for the finest observations, the degrees are still farther sub-divided into spaces of 5′, 3′, or even 2′. Since there are 360° in a circumference, it follows that in a division to 2′ there will be 10,800 of these graduations, or fine marks, on the circle. These marks must all be as nearly equi-distant as human art can make them, and the problem of doing this, together with that of making them so fine and sharp that they

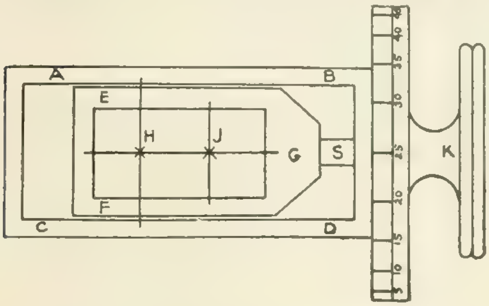

FIG. 4.

can be used in the most precise measurement, is one of the most difficult with which the instrument maker has to deal. The way in which the divided circle is used to measure the angular motion of the telescope is shown by the dotted outline of the latter. The circle is attached to it so that both move on an axis concentric with the circle and perpendicular to its plane. Then, when the telescope is turned on this axis, the circle turns with it as a grindstone does on its axis. The distance through which telescope and circle are turned is then measured by means of the graduations. To show how this is done, other appliances must be described.

Instead of two stars being far apart, so that the telescope has to be moved, they may be alongside of each other, as in Fig. 2; then, the observer, by moving the cross-threads from one star to the other, and measuring the amount of the motion, can determine the angular distance between the stars, and their relation to each other. This is done by a micrometer, one kind of which will now be described.

The Filar Micrometer.— This adjunct is so called because an essential part of it consists in fine threads of spider lines stretched across the field of view, as already described. The aim of its construction is to admit of these threads being moved in a direction at right angles to their length, by a very fine screw, so that the space over which they pass may be measured by the turns of the screw. The principal appliances for effecting this are a fixed frame, A B C D, Fig. 4, in which slides another frame, E F G, moved by a fine screw at S. Across this inner frame is stretched the spider line J, and across the fixed one the spider line H. To the head of the screw is attached a cylindrical rim, which has 100 or some other number of divisions cut upon it. An index mark serves to show how far the screw is turned. An apparatus for measuring the number of turns of the screw is attached, but need not be described here. Then when the observer turns the screw, the movable frame of the spider lines is slowly carried along with it. The position of the spider lines as they move is then shown at every moment by the number of turns of the screw and the fractions of a turn. To show the accuracy with which this can be done, we remark that the screws used by astronomers may have 100 or even 125 turns to the inch. Then, each revolution of the screw, as read off on the head, measures to a motion through this space. There being 100 graduations on the head, each graduation may measure the motion of 1-10,000 of an inch. But the observer may estimate the tenths between the divisions, thus carrying his measurements down to the 1-100,000 of an inch. Beside the movable spider line across the frame, fixed spider lines may also be stretched across the fixed frame. Then we shall have two systems of spider lines, one movable and the other fixed. The relation of each to the other is measured by the turns of the screw.

To determine the exact position of the graduated circle, a filar micrometer O is attached to a microscope of the form shown in Fig. 5, and the latter is finally fastened to a fixed frame in such a position that, when the observer looks into the microscope, he sees the graduations on the circle magnified as many times as necessary, and also the threads of the micrometer. The microscope being fixed remains at rest while the circle turns. If the instrument were geometrically perfect in every respect, one reading microscope would answer

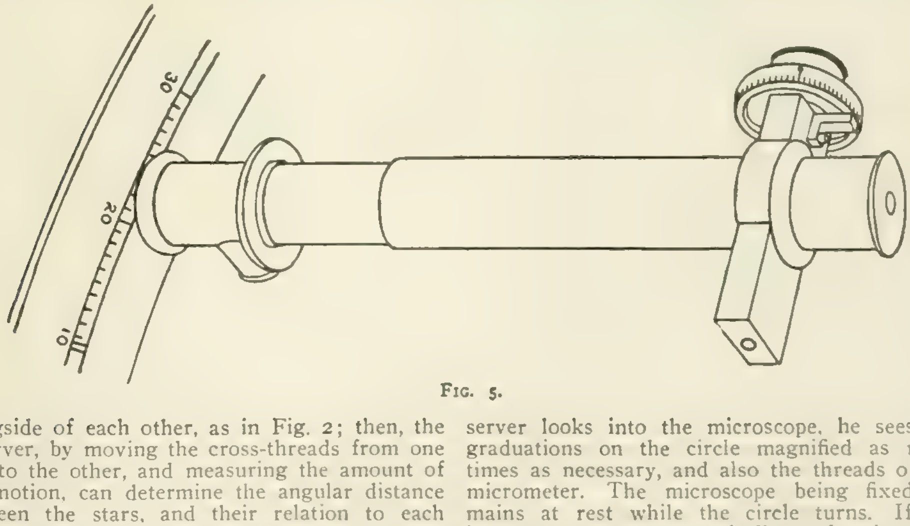

FIG. 5.

the purpose; but, as the circle cannot be centred with mathematical exactness, pairs of microscopes are used which are at opposite ends of diameters of the circle. For example, when the graduation 15° 20′ is brought under one microscope, the graduation 195° 15′ would be under the opposite one. It is customary, for greater precision, to have two such pairs at right angles to each other, or four microscopes in all.

To determine the position of the circle, and hence the direction in which the telescope attached to it points, the observer looks into one of the microscopes and fixes upon some graduation of the circle, turns the micrometer screw till a spider line, or the middle of a pair of lines is central on the graduation, and then reads the indication of the head of the screw. It will be noticed that in Fig. 5 the mark 21° is central under the microscope. By pointing his telescope on one star after another and reading the microscope in this way, noting on each occasion what graduation is read, the distance through which the telescope is moved, and therefore the angles between the stars, are measured with the highest precision.

The Clock.— The astronomical clock does not differ greatly in its construction from the ordinary clock. Its arrangement and the numbers on its face are, however, adapted to the measures of time used by astronomers. Mean solar time, which is the time we make use of in the affairs of daily life, is also used by the astronomer with a slightly different arrangement. Instead of the hours being designated as A.M. and P.M., the astronomer counts through the whole 24 hours. Moreover, the count does not begin at midnight, but at noon, which is therefore the commencement of the astronomical day. For purely scientific purposes this is the natural time to begin the day, because it is determined by the passage of the sun across the meridian. Therefore, any day of the month, as used by the astronomer, continues until noon of the following day, when a new day begins. For this reason the hour hand of his clock only makes one revolution in the 24 hours, the hours being numbered from 0 to 23. The astronomer makes use of a second system of time, entirely different from that used in daily life, being based on the apparent diurnal movement of the stars. We have explained, in the preceding article (ASTRONOMY) that the time between two passages of the same star over the meridian of a place is not quite 24 hours, but nearly four minutes less. This is the true time of rotation of the earth on its axis, because, in consequence of the advance of the earth in its orbit it must go through a little more than its true revolution in order that the meridian of any place on its surface — that of Washington for example — may again pass directly under the sun. The astronomer therefore uses a "sidereal day," which is shorter than the day determined by the sun in the proportion 365.24:366.24. This day is divided into 24 sidereal hours, and each hour into sidereal minutes and seconds, according to the usual system. A sidereal clock is regulated so as to gain about 3 m. 56 s. every day on our ordinary clocks and, in this way, keep time with the apparent diurnal movement of the fixed stars. It is so set that it shall read 0 h., 0 m., 0 s. at the moment when the vernal equinox crosses the meridian. As any of us, by looking at the clock, can tell, by the time of day, whether the sun is in the east, south, or west, so the astronomer, by his sidereal clock, can tell in what part of its apparent diurnal course any star may be situated. For examples, at 5 h. he knows that the constellation Auriga is on the meridian, and at 18 h. 30 m. that the beautiful Lyra is crossing the meridian.

The Chronograph.— There are two systems by which the astronomer notes the time of occurrence of an instantaneous phenomenon to a fraction of a second. On the older system, which is not without its advantages, the observer, looking at his clock, counts its beats until the occurrence of the phenomenon he is to observe. We may take, as an example, the occultation of a star by the moon. He sees the limb of the moon approaching the star until it is clear that, in a few seconds, it is going to pass over it and hide it from view. Then, looking at the clock, he listens to the seconds, mentally counting the number of each beat. At length, there is a certain beat of the clock when the star is not yet hidden, while before the next beat the star has disappeared from view. He estimates how many tenths of the interval between the beats of the clock had elapsed when the star disappeared, and records the hours, minutes, seconds, and tenths in his note-book. The skilled observer will seldom be more than a few tenths of a second in error in this estimate. It requires long practice, and much natural aptitude, to be able to make an accurate observation in this way. The method has also the inconvenience that there is no permanent record except that which is written down at the moment, so that, if the observer has made an error of any kind, he has no direct way of detecting it except by subsequently discovering that something must be wrong. This difficulty is avoided by means of a chronograph. In the form commonly used, the chronograph consists essentially of a cylinder, generally about eight inches in diameter and one or two feet in length, revolving on its axis by clock work at the rate of one turn a minute. Around the cylinder is stretched a sheet of paper, which is carried with it in its motion. The sheet is pressed by a pen, pencil, or other point, so as to leave a mark on the paper as the cylinder revolves. The pen is carried by a little carriage moving slowly forward from one end of the cylinder to the other at a rate of about one tenth of an inch, or a little more, in a minute. Consequently, the point describes a spiral line on the paper as the chronograph goes through its successive revolutions, until the pen arrives at the farther end of the cylinder. This may take a period of two, three, or four hours, according to the adjustments. The pen is connected with an electro-magnet, the current around which passes through the works of the clock. The arrangement is such that at every beat of the clock, or sometimes at every alternate beat, the electric current is either closed or broken. With each closing or breaking of the current a slight motion is given to the pen so that the seconds are marked on the paper on the revolving cylinder. The same or another current also passes through a key held in the hand of the observer. When the latter sees the moment of the phenomenon he is to note approaching, he holds the key in his hand, and presses it at the exact moment to be recorded. A motion is thus given to the pen, and the posi-

tion of the signal on the paper among the signals given by the clock shows the moment to a fraction of a second at which the signal was given.

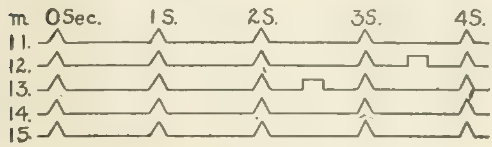

FIG. 6.

Different systems are used based on this general principle. There are various ways in which the pen marks the clock beats on the paper. In that mostly used in this country the pen is not raised from the paper, but is given a sudden lateral jerk, producing a notch in the line, as shown in Fig. 6, which is a copy of a small portion of a chronograph record. On another system the pen simply makes dots on the paper at each beat of the clock. Sometimes the current passes around the electric magnet all the time except at the instant a signal is made. Then one and the same electric circuit is used for both the clock and the observer. Sometimes the clock only makes the circuit at the moment of its beat; then the circuit at the command of the observer is a second one, which he makes by pressing the key. The main point in all systems is that the beginnings of the minutes all come under each other so that, by taking the sheet off of the cylinder, and spreading it out, writing in the minutes and the lines of seconds, the observer can determine the exact moments at which every one of any number of signals were made while the chronograph was running. For example, in Fig. 6 it will be seen that the observer pressed the key at 12 m. 3.5 s. and again at 13 m. 2.4 s.

The Spirit Level.— Another appliance much used in astronomy is the spirit level. It serves to set the axis of an instrument exactly horizontal. It consists of a glass tube, generally six or eight inches long, of which the rounded surface is not a perfect cylinder, but is formed by the revolution of the arc of a very large circle around its chord. The tube is therefore of the shape shown in Fig. 7, slightly larger in the middle part than at the two ends. The amount of bulging is, however, so slight that the eye cannot perceive it. In the most delicate levels, a section of the curved surface is an arc of a circle perhaps half a mile, more or less, in diameter. The tube is nearly filled with chloroform or ether. Water, or even alcohol,

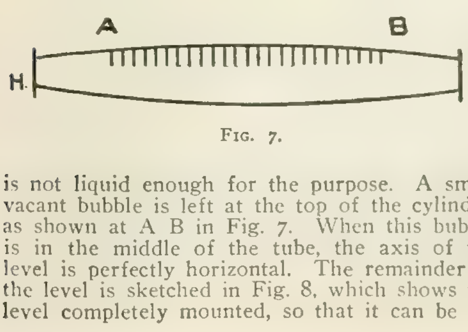

FIG. 7.

is not liquid enough for the purpose. A small vacant bubble is left at the top of the cylinder, as shown at A B in Fig. 7. When this bubble is in the middle of the tube, the axis of the level is perfectly horizontal. The remainder of the level is sketched in Fig. 8, which shows the level completely mounted, so that it can be set on the horizontal pivots of the instrument of observation. The true horizontality of the pivots is tested by reversing the level end for end, reading the position of the bubble at each

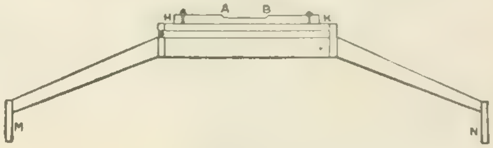

FIG. 8.

setting. Details need not be entered into at present, as we only wish to make the principle of the instrument clear. Nearly all instruments for astronomical measurement are made by putting together some combination of the devices we have described. The two combinations most used in astronomical observatories are the Meridian Circle or Transit Circle, which are the same in principle, and the Equatorial Telescope.

The Meridian Circle.— This instrument is used for two distinct purposes. One is the determination of the right ascensions of the heavenly bodies; the other the determination of their declinations. It will conduce to clearness to consider these two functions separately and begin with the instrument as adapted to the first purpose. In this form it is called the transit instrument and is shown in Fig. 9. It consists essentially of a telescope, mounted on a

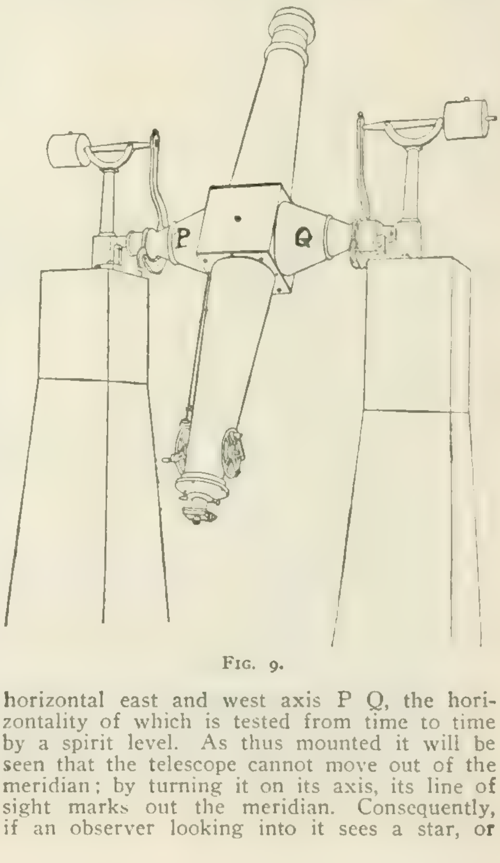

FIG. 9.

horizontal east and west axis P Q, the horizontality of which is tested from time to time by a spirit level. As thus mounted it will be seen that the telescope cannot move out of the meridian; by turning it on its axis, its line of sight marks out the meridian. Consequently, if an observer looking into it sees a star, or

other heavenly body, he knows that the star must be near the meridian. To make the observation more exact, a system of spider lines, shown in Fig. 10, is stretched across the focal

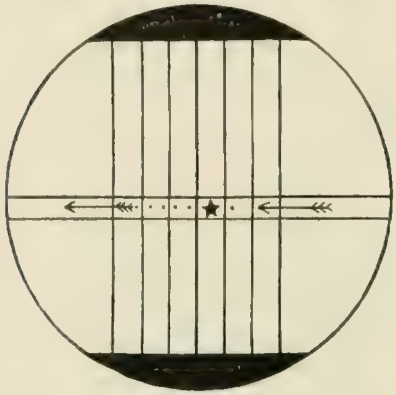

Fig. 10.

plane, as already described. The middle line is so adjusted as to mark the meridian with the greatest possible exactness. The result is that the observer, looking into the instrument, sees these spider lines, and he may also see a star moving toward the meridian by virtue of its apparent diurnal motion as shown in the figure, where it is about to cross the meridian line. Watching it with a key connected with the electric circuit of the chronograph in his hand, he taps the key at the moment the image of the star crosses each of the lines. The middle line marks the passage across the meridian. The other lines are used in order to secure greater exactness by taking the mean of all the transits across the separate lines. Thus, by pointing his instrument into any part of the meridian, the observer may determine the times by his sidereal clock at which any number of stars crossed the meridian of his place.

In order that the line of sight of the instrument may describe the true meridian, it is necessary that, when the instrument is turned in the proper direction, the line shall pass

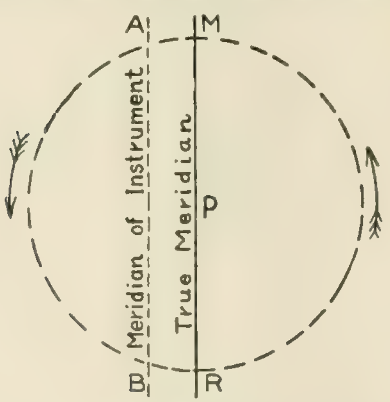

Fig. 11.

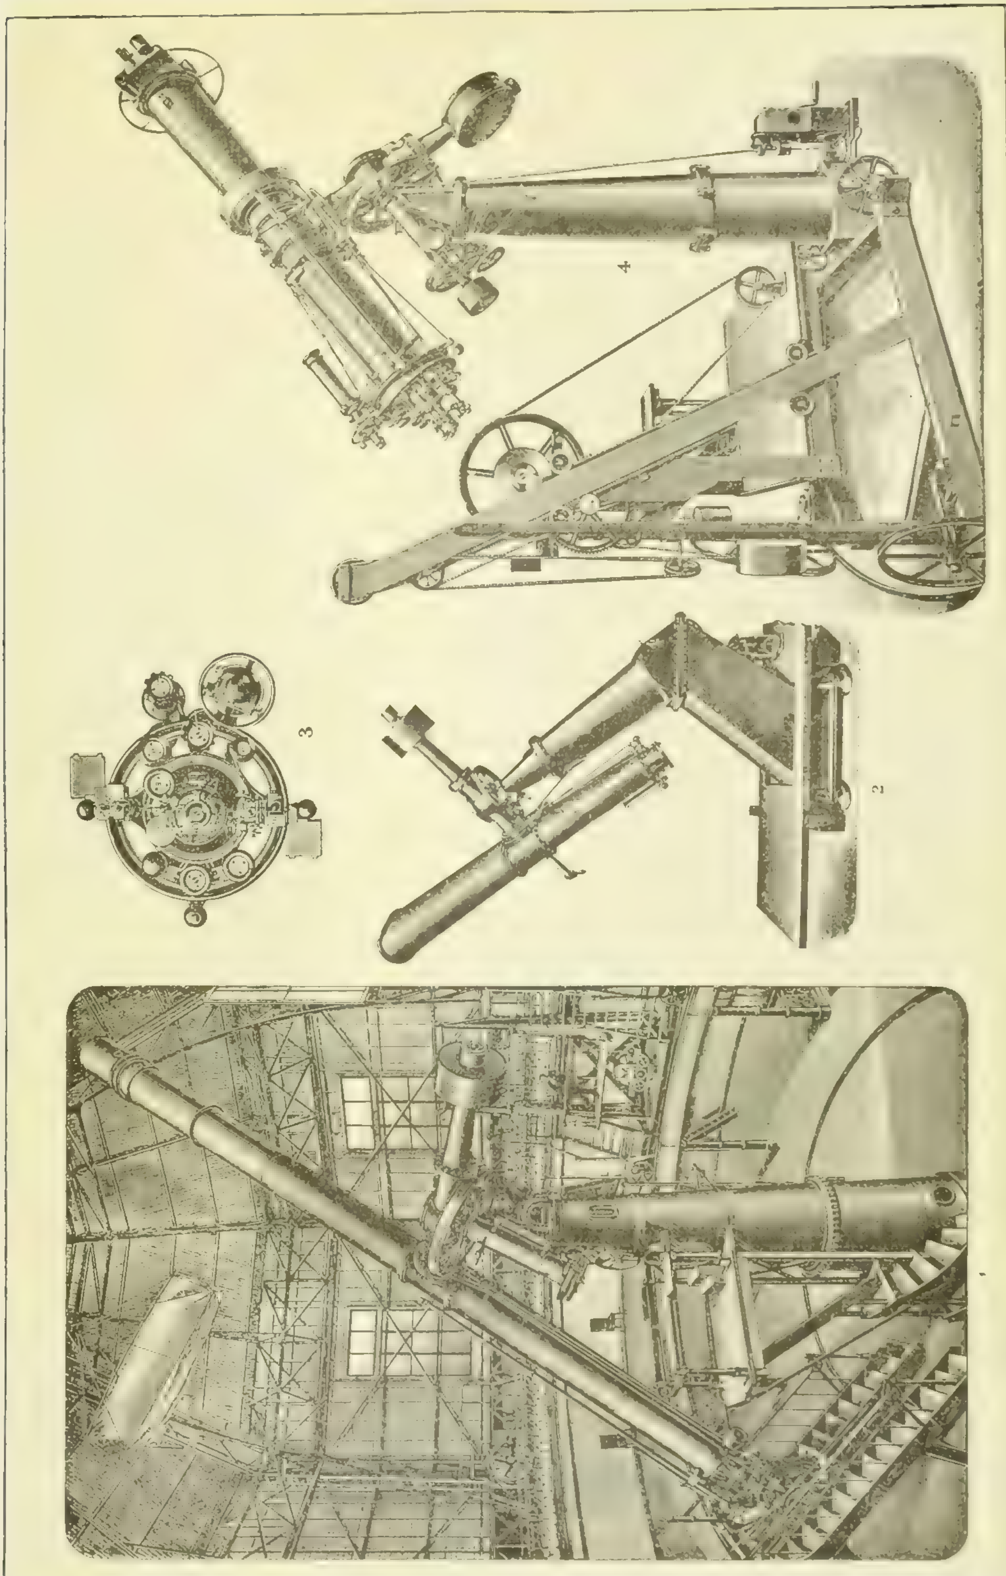
through the celestial pole. This is effected by the following arrangement: In the course of its apparent diurnal motion, a star near the pole will cross the meridian of any place twice in the course of a sidereal day, first above the pole and then below it. Let the dotted circle in Fig. 11 be its apparent diurnal circuit around the pole P. Let the vertical line M R be the true meridian passing through the pole, and the other line A B that marked out by the line of sight of the transit instrument, supposed not to be exactly in the meridian. Then the star will take a less time in passing around from A to B on the left than in the other part of its course from B to A. Therefore by observing the transit both above and below the pole, across the middle thread of the instrument, the observer determines whether the line of sight of the instrument passes east or west of the pole and may adjust it accordingly. It may be said that, in astronomical practice, no instrument is ever assumed to be perfectly adjusted. The clock of the astronomer is never assumed to be correct, nor his transit instrument to be in the true meridian. What he does is, assuming them wrong, to make his observations, determine the errors, and correct his observations accordingly. This is called "reducing" the observation. We have already explained that, when a star is exactly in the same hour circle with the vernal equinox, its right ascension is 0 h., 0 m., 0 s. Since the clock, assumed to be correct, then reads exactly 0 h., it follows that the star in question will cross the meridian at this time by the clock. Then, as the sphere revolves, the right ascensions of the stars are all equal to the sidereal time at which they cross the meridian. Thus the observer by noting these times, measures the right ascensions of the heavenly bodies. This system of using the clock instead of a divided circle for determining right ascensions constitutes one of the greatest advances ever made in astronomical measurement. It depends upon the perfect uniformity of the earth's rotation and the excellence with which a clock can be made.

The Meridian Circle is the transit instrument, just described, with one or two graduated circles on its axis of rotation. The method of using it, and determining the arc through which the circle has moved at any time has already been explained. The inquiring reader may wish to know how, by such readings, the astronomer can determine the declination of stars. If the celestial pole were a visible point in the heavens, this would be very simple; the observer would turn his instrument until it pointed exactly at the pole, and then read his microscopes. Then as one star after another crossed the meridian, he would make a similar pointing, reading his microscope for the transit of each star. The difference between the reading on the pole and that on the different stars, would show their distances from the pole. Subtracting each of these from 90° would give the declination of the stars as seen in the instrument.

But, unfortunately, the pole is not a visible point. The observer has therefore to refer his position to the direction of gravity, which is done by a very ingenious use of a basin of quicksilver. The basin is set on a firm support on the ground under the telescope, and the latter is pointed directly downward. The observer, by mounting up to the eye-piece and looking down, is looking perpendicularly into the basin of mercury. A combination of reflectors is then arranged in the eye-piece of the



1. Equatorial in the Observatory at Pulkova. 2. Photographic Refractor. 3. Eye-end of No. 4. 4. Heliometer.

telescope so that he can, at the same time, see the threads in his eye-piece and the images of these threads as reflected from the basin of mercury. When a telescope is so adjusted that the image and the thread coincide, he knows that the line of sight of his telescope is truly vertical. He then reads the microscope of his circle and so determines what the reading of his circle is for the vertical position. He knows that if the telescope is pointed at the zenith, the reading will be different by exactly 180°. He thus determines the exact distance at which the heavenly bodies crossed the meridian north or south of his zenith. From this, the determination of the declination is, in principle, a simple matter.

The Equatorial.— One of the most important arrangements of nature with which the astronomer has to deal is the diurnal motion. This takes place so slowly that, in looking at the stars, we do not notice it unless we watch for some time. But, if we point a telescope at a heavenly body, it magnifies the diurnal motion as much as it does the object. The result is that such a body, seen in a fixed telescope, is continually traveling across the field of view, and the instrument has to be continually moved to keep up with it.

In order to avoid this inconvenience, it is necessary that, if measures are to be made upon the body, or if it is to be continuously studied, the telescope must move to correspond. This is brought about by mounting it upon an axis parallel to that of the earth, and therefore oblique to the horizon, called the polar axis. The inclination to the horizon must be equal to the latitude of the place. All great telescopes are thus mounted. The way in which this is done will be seen by the accompanying picture of the great telescope mounted at Pulkova, Russia. In order to keep the telescope pointed at the object, it must be turned upon the polar axis by clock work, moving it steadily at a rate equal to the diurnal motion of the object observed. In reality, the telescope is then pointed in a fixed direction, the motion of the earth being simply neutralized by the clock work of the telescope carrying the latter in the opposite direction. The equatorial telescope must also have a second axis, called the declination axis, in order that it may be pointed at stars in different declinations. The direction is determined by circles attached to the telescope, which show, at any time, to what declination on the celestial sphere the instrument is pointed. By a combination of contrivances, the astronomer can point his telescope by day at any star bright enough to be visible in it; or, by night, at any object invisible to the naked eye, of which he knows the right ascension and declination. He first turns his telescope until one divided circle corresponds to the declination of the star, and then clamps it in that position. Then, looking at his sidereal clock, and taking the difference between the sidereal time and the right ascension of the star, he turns his telescope on the polar axis until the other circle shows the correct pointing. Then he starts the clock work which sets the telescope in motion, and looking into the eye-piece, sees the required object. Every large telescope is also supplied with a finder. This consists of a smaller telescope fastened to the larger one in such a way that the centre of the field of view is the same in both. But the finder has a lower magnifying power, and therefore a much larger field. Looking into it, and recognizing the object he wishes to observe, the observer moves the telescope until the object is seen on the cross threads of the finder. Then he knows that it is in the field of view of the large telescope.

Application of Photography to Astronomy.— From the time that photographic methods were introduced, the idea of taking pictures of the heavenly bodies by such methods must have occurred to astronomers. About the year 1840, Prof. J. W. Draper of New York put this method into practice by taking a daguerreotype of the moon. Shortly after our present system of photography was devised, several American astronomers carried the experiment yet farther. Notable among these were G. P. Bond, first assistant and afterward director of the Harvard Observatory; and L. M. Rutherfurd of New York, who was the possessor of an excellent telescope, and brought the method to a high state of perfection.

The principle on which a photograph of a heavenly body is taken is extremely simple. A telescope is pointed at the body so that the image of the latter is formed in its focus. A sensitized plate is placed in the focus and exposed for the necessary time. This may be only a fraction of a second, or it may be several hours. Unless the exposure is very brief, it is necessary that the telescope shall be kept in motion, so as to follow the object in its apparent diurnal course. When the exposure is completed, the image is developed in the usual way. In photographing, the ordinary telescope, as used for eye observations, is not well suited to the purpose, for the reason that the chromatic aberration is not the same for the visual and for the photographic rays. It is necessary to have a somewhat stronger crown lens, or a weaker flint lens, if a telescope is to be used in photographing, than if it is to be used by the eye. But the necessity of having telescopes of the two kinds is now, to a certain extent, done away with by the use of sensitized plates which are especially sensitive to the visual rays. By putting in an absorbing screen, through which the rays must pass before they reach the focus, and which allows only the visual rays to pass, very accurate photographs can be taken by the plates. This defect is felt only in the refracting telescope. A reflecting telescope brings all the rays, of whatever color, to one and the same focus, and therefore may be used either for photographing or for seeing. Improvements made in recent times in the sensitiveness of photographic plates have given an enormous extension to this method in astronomy. It is now found that celestial objects completely invisible to ordinary vision can be photographed. While only a few thousand nebulæ have been catalogued as visible to the naked eye, it is found that there are hundreds of thousands which admit of being determined by photography.

The latter is now employed for two distinct purposes. The first is simply that of forming a picture of the sky, or rather of the stars in the sky. For this purpose the best telescope is one as large as can conveniently be obtained, but of short focal length. A great enterprise in this direction was started in 1887 by an association of astronomers who met at the Paris Observatory, and put into operation a plan of photographing the entire heavens on from 10,000

to 20,000 plates, each two degrees square. This work is now approaching completion, and is intended to form a permanent record of the starry heavens, as they are seen in our times. A similar object is reached on a different system at the Harvard Observatory. There photographs are being constantly taken with telescopes much shorter than those used for the international chart. In this way new stars are from time to time discovered, and variations in the light of different stars are brought out. The other purpose is that of exact measurement. When the astronomer had to determine the respective distances of stars in the same field of view, he has hitherto generally depended on the filar or other micrometer. The use of this instrument is laborious. When the photographic method is used, he simply takes a picture of the stars he wishes to measure, and, at any convenient time, places it under a measuring engine supplied with sliding microscopes, and measures off the distance on his negative. The result of these two applications is that photography is now slowly supplanting eye observations in an important fraction of the astronomical work of the world.

SIMON NEWCOMB, LL.D.,
Washington, D. C.

Astronomy, Theoretical. This branch of the science grows out of the great discovery of Newton, that the motions of the heavenly bodies, especially those of the solar system, are determined by their mutual gravitation. The results of this theory are now worked out by purely mathematical methods with a degree of precision scarcely attainable in any other branch of science. The adopted method consists first in expressing the attraction or pull experienced by each body from all the others in the form of differential equations. These equations express, in the most general way, the acceleration which the planets experience at every moment from the attraction of the other bodies. We do not write them because they would be understood only by a reader expert in the calculus, who, if he desires to be acquainted with them, will consult special treatises. It will suffice to say that there are three differential equations for each planet, which express the attraction, and its effect on the motion of the planet at any instant, in the direction of three co-ordinates. The problem then becomes the purely algebraic one of integrating these equations. The result of this process is that the effect of the attraction or pull upon the body, through a period of days, years, or even centuries, is summed up with great exactness, so that the motion of the body through the whole period can be expressed by algebraic equations. The simplest case occurs when there are only two bodies. The integration shows that, in this case, the bodies revolve round their common centre of gravity in orbits each of which is an ellipse. Commonly it is necessary to consider only the motion of the smaller of the two bodies, the motion being defined as if the larger were at rest. This is the case of a planet revolving round the sun, or of a satellite round its primary. It is then found that the orbit described by the revolving body round the great central body is an ellipse having the latter in one of its foci. The motion is also found to be subject to two other laws which bear the name of Kepler, their first discoverer. One of these is that the radius vector, that is to say, the line drawn from the central body to the other sweeps over equal areas in equal times. The result of this is that if A B be the orbit having the sun, S, in the

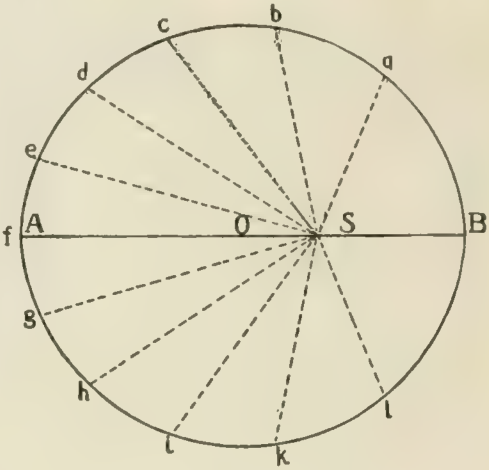


FIG. 12.

focus; and if we mark on the orbit the points *a*, *b*, *c*, etc., which the planet passes through at any equal intervals of time, and then draw lines from each of these points to the sun, the areas included between these lines will all be equal to each other. A glance is sufficient to show that the nearer the body is to the sun the more rapidly it must move.

The position of the orbit and the place of the body in it are determined by six quantities called *elements*. Two of these elements express the position of the plane in which the ellipse lies, and therefore in which the planet moves. These are the inclination of the plane of the orbit to some other plane taken as that of reference. For the latter is commonly adopted the plane of the ecliptic, in which the earth revolves round the sun. When the inclination of the orbit of any other planet is spoken of, the astronomer means the angle which the plane of its orbit makes with the plane of the ecliptic. The other of the two elements expresses the line passing through the sun along which the two planes intersect. This is called the Line of Nodes. The position of the node is defined by the angle, as seen from the sun, between the vernal equinox and that node where the planet crosses from the south to the north side of the ecliptic. Three other elements determine the size and form of the elliptic orbit, and its position in its plane. The semi-major axis, A B, of the ellipse is called the mean distance of the planet from the sun, it being half the sum of the greatest and least distances. The other of these elements is the eccentricity of the orbit, which is equal to the quotient obtained by dividing the distance of the sun, O S, from the centre of the orbit by O A, the semi-major axis. These two elements completely determine the ellipse. The exact position of the ellipse in the plane may then be defined by the angle which the semi-major axis, O B, makes with the line of the nodes. It will be seen that the point B is that at which the planet is

nearest to the sun. This is called the perihelion of the orbit if the central body is the sun; if the earth is the centre, the perigee. The opposite point, A, where the planet is most distant, is called the aphelion, or apogee. Finally, the sixth element defines the position of the planet at some given moment of time.

The time of revolution of the planet is given by Kepler's third law, which is that the squares of these times are proportional to the cubes of of the major axes of their orbits. For example, let one planet be four times as far as another from the sun. The cube of 4 is 64. The square root of this is 8. It follows that the planet which is four times as far will be eight times as long in completing its circuit. If the outer planet went as rapidly as the other, it would be only four times as long. Its orbital motion is therefore, on the average, only about half as rapid.

In theoretical astronomy a unit of distance is necessary. Our ordinary units do not well serve the purpose of the astronomer for two reasons. They are too short for the great distances he has to measure, and the magnitude of the heavens in terms of miles is not known with sufficient exactness to make that measure convenient. What the astronomer does therefore is to take the mean distance of the earth from the sun as his yardstick, and to express the distance of all the bodies of the solar system, both from the earth and from each other, the moon sometimes excepted, in terms of this unit.

From the laws of motion based on gravitation may be derived several interesting theorems. Finally, suppose, that at some point in the solar system,— we may take, to fix the ideas, a point at the mean distance of the earth from the sun,— a number of bodies are projected in different directions, but all with the same velocity. Then, the equations of motion show that the major axes of the orbits which these bodies describe will all be equal. Then, from Kepler's third law it follows that the times of revolution will also be equal. Consequently, at the end of a certain period the bodies will all return at the same moment to the point from which they started. This period will depend only on the velocity with which the body is projected. There is a certain velocity, called the circular velocity, which is such that if the bodies are projected in a direction at right angles to that of the sun, they will describe circular orbits. If all the bodies are projected in different directions with this same velocity, they will all be exactly one year in getting around and returning to the starting point. Now suppose that, instead of the bodies being projected with this circular velocity, which is very nearly that of the earth in its orbit, they are projected with a somewhat smaller velocity. Then, the less the velocity the less the major axis of the orbit, and the greater the velocity the greater the major axis. A body projected with a speed one-third greater than that of the earth would fly out beyond the orbit of Jupiter. A slightly greater speed would carry it beyond the orbit of Neptune, the reason being that, as the body recedes, the attraction of the sun diminishes at so rapid a rate that the weak attraction left is not sufficient to overcome the slight surplus velocity. Finally, if the speed is equal to that of the earth multiplied by the square root of 2, that is to say, about 26 miles per second, the body will never return. The ellipse in which it should move is stretched out into a parabola, still having the sun in its focus. If the velocity is greater than this, the parabola will be still farther changed into a hyperbola. Then the body would fly out into the stellar spaces, perhaps in the course of millions of years reaching some other sun, but would certainly never return to our system. Another theorem is that the velocity, no matter what the form of the orbit, diminishes as we go out from the sun in proportion to the square root of the distance. This we have already seen by Kepler's third law, when we found from that law that a planet four times as far from the sun would move only half as fast. Thus the parabolic velocity is less the farther a body is from the sun. At the planet Uranus it is less than six miles per second; at that of Neptune, about five miles per second. Still another theorem is that if a planet moving in a circular orbit were stopped at any point of its motion, and then were allowed to drop toward the sun, the time of reaching the sun would be equal to that of revolution divided by the square root of 32. It follows that if the earth should be stopped in its motion, it would drop to the sun in a number of days found by dividing 362.24 by the square root of 32. This would be nearly 64 days.

The orbits of most of the large planets are nearly circular. For particulars relating to them see SOLAR SYSTEM. The orbits of comets are, however, mostly parabolas, or ellipses which cannot be distinguished from parabolas when the comet is near enough to the sun to be visible. It is probable that many of those orbits which are ellipses have become so through the comet at some time in its history passing very near a planet. (See COMET.) One of the problems of theoretical astronomy which the astronomer often meets with is that of determining the orbit of a newly discovered body of the solar system. Three complete observations of such a body, that is to say, three observations each of which determines exactly the apparent position of the body on the celestial sphere, enable the astronomer to determine the orbit in which it is moving round the sun. The calculation requires from five to ten hours' work by an expert calculator having at his command the necessary tables. The first orbit thus computed may be considerably in error, because the effect of errors of observation is multiplied many fold, unless the planet has moved through a considerable arc of its orbit between the times of observation. But the longer the planet is observed, the more exactly the elements of its orbit can be determined. It is found that when two stars are so near each other as to be kept together by their mutual attraction, they revolve around each other in an elliptic orbit. It follows that the law of gravitation extends to these systems. Thus the calculations of the theoretical astronomer are not confined to the solar system, but may be extended to the fixed stars.

In all that precedes we have considered only the motion of two bodies, the smaller of which moves around the larger in an elliptic orbit. But, as a matter of fact, every planet of the solar system is acted upon not only by the great central body, but by every one of the other

planets. The result is that the actual orbit, although very nearly an ellipse, deviates slightly from it, and the motion is not exactly in accordance with Kepler's laws. The problem of taking account of these additional forces is an extremely complicated one, in which success has been reached only by successive generations of the ablest mathematicians devoting long years of study and calculation to the subject. While the solution, even to-day, is far from complete, it has been so far advanced that it is possible to prepare tables of the motions of the planets which shall hold good for generations, and even for centuries. The method in which the problem can best be solved was devised by Lagrange, who flourished in France toward the latter part of the 18th century. The fundamental idea of his method was that the motion of the planet at every instant should be represented by an ellipse, but this ellipse continually changes its form and dimensions so as to fit in with the actual motion of the planet under the influence of the attraction of all the other planets. Some idea of the case may be imagined by supposing a cord of some light material made into an ellipse very nearly a circle, and left to float on the waves of the ocean. Then we should see the cord, while still remaining almost in its original shape, continually bending and twisting as it was moved by the waves. So does the variable ellipse in which the planet moves. It is exactly defined by supposing that, at any one instant, the attraction of all the other bodies, the sun excepted, ceases. Then the planet would move in a fixed and unchangeable ellipse. This ellipse is taken as that which corresponds with the motion of the planet at the instant. At a second instant the planet would actually have deviated slightly in consequence of the attraction of the other planets, but there would still be a corresponding ellipse, but somewhat different. So the ellipse goes on changing continually.

When these changes are subjected to the rigor of mathematical formula, it is found that they nearly, but not quite, compensate each other in the long run. Let us take, for example, the eccentricity of any one orbit. This will vary in the course of every revolution of the planet, and may come back to its original amount any number of times. But, if we watch it revolution after revolution, we shall find that, in the long run, it continually increases or diminishes. It is thus found that the eccentricity of the earth's orbit has been diminishing through all historic times, and this diminution will go on for 43,000 years to come. Moreover, the general rule is that the perihelion of the planet is gradually moving forward. In the case of the earth's orbit the motion is such as would carry it all the way round the circle in 200,000 years. The inclinations and longitudes of the nodes are also varying in the same way. These variations, which go on century after century, are called secular variations, while those which are compensated from time to time are called periodic. Now, the most interesting and important question of celestial mechanics is whether the secular variations will continue forever in the same direction. The profound analysis of Laplace and Lagrange shows that such will not be the case so far as the eccentricities are concerned. At the end of immense periods the direction will be reversed. It is now known that the diminution of the eccentricity of the earth's orbit after continuing for about 43,000 years will change to an increase for a certain period. It is thus with all the orbits; the motions go through a series of oscillations having periods of hundreds of thousands of years — like "great clocks of eternity which beat ages as ours beat seconds." The precision with which the astronomer is now able to predict the motions of the heavenly bodies is reached by a combination of mathematical computations of the most difficult and complicated character, with the most refined observations upon the positions of the moon and planets, year after year.

The most complex of all the problems is that of the moon's motion around the earth, of which we shall mention some features. In this case the central body, the earth, is vastly smaller than the sun. But, owing to the great distance from the sun and the consequent small difference in the force of its attraction upon the earth and moon, it happens that the moon revolves around the earth in an orbit which approximates to an ellipse. But the changes and motions in this ellipse are much larger and more rapid than in the case of the planets. For example, the perigee of the moon's orbit makes a revolution round the earth in eight years, while the node on the ecliptic makes a revolution in 18.6 years. The moon also makes two swings back and forth during the space between two full moons, and the eccentricity and perigee both make an annual swing, all owing to the action of the sun. See Moon.

The principles of theoretical astronomy, and the operations of practical astronomy are combined in one of the greatest achievements of the human intellect — that of measuring the heavens and weighing the planets, and, in a few cases, even the fixed stars.

The distance of the moon is determined in two ways, the results of which agree within the necessary range of uncertainty of the methods. One is by the measurement of the moon's parallax, taking as the base line two distant observatories, Greenwich and the Cape of Good Hope. (See Parallax.) The other method consists in determining exactly what ought to be the size of the moon's orbit in order that she may make her revolution around the earth in the time that she actually does. The probable error of the distance of the moon at any time, as determined in this way, is not more than 40 or 50 miles.

The proportions between the orbits of the several planets are known with the greatest exactness from their observed times of revolution, and from Kepler's third law. It follows that if we can get the exact distance of any one planet at any one time, all the other distances in the solar system may be derived by the known proportion. The fundamental quantity which is used as a unit of measure is the distance of the sun. This distance has been determined by four completely separate and independent methods, the agreement between which illustrates the great exactness of astronomical theory.

The first method is by measures of parallax. The application of this method is fully described in the article Parallax. It requires that the apparent direction of a planet among the stars

be observed with great exactness from two far distant points of the earth's surface, or at two times of day during the interval between which the observer is carried around by the rotation of the earth. These observations have to be on a planet and not on the sun, because the latter, owing to the brilliancy of its light, cannot be measured with the necessary precision. The most celebrated way of determining parallax has been by observing transits of Venus (q.v.). But these occur at such rare intervals, the last having been in 1882, and there being no other to occur during the 20th century, that the measures have to be made on other planets which approach nearest to the earth. For this purpose Mars has sometimes been used, because it occasionally approaches us within less than half the distance of the sun. But the most exact observations can be made on some of the minor planets at the time of their nearest approach.

The second method is by the velocity of light. This method is, in principle, the most simple and elegant of all. It rests on the fact that it is possible, by two kinds of observation, to determine how long it takes light to pass from the sun to the earth, or to cross the earth's orbit. If then we can determine by measures on the earth's surface how fast light travels, it follows that by multiplying this velocity by the time it takes to travel from the earth to the sun, we shall have the distance of the sun. The velocity of light has actually been determined with great precision by means of the revolving mirror. (See LIGHT, VELOCITY OF.) The result is a speed of 186,300 miles per second. The time required for light to cross the earth's orbit is much more difficult to determine. The only way in which a direct determination can be made is through observations of the eclipses of Jupiter's first satellite. By comparing the times of these eclipses through a long series of years when Jupiter is at various distances from the earth, it is found that the eclipses are seen later, the farther Jupiter is from the earth at the time. This is because light requires time to travel over the different distances. But the determinations made in this way are not very exact, because such eclipses take place so gradually that it is impossible to fix upon a precise phase without a possible error of several seconds. All we can say as a result of this method is that it takes about 4 m. 20 s. for light to pass from the sun to the earth.

A more exact result is reached by measuring the displacement of the fixed stars produced by aberration. As the earth makes its annual course around the sun, the position of every star in the heavens is, at every moment, slightly displaced toward the direction in which the earth is, at the moment, moving. This is due to the proportion between the velocity of light and the speed of the earth in its orbit. Unfortunately, the speed is so great that the displacement in question is only about 20.5″; an arc too small to be determined with the precision that is desirable. Still, the observations available are so numerous that the result, 20.525″, found by Chandler, is probably within one, or, at most, two hundredths of a second of the truth. Accepting Chandler's number, light requires 500 seconds to pass over the distance which separates the sun from the earth. Multiplying this by the speed of light, we have, for the distance of the sun $186,300 \times 500 = 93,150,000$ miles as the distance of the sun.

The third method is a very recondite one, because it rests on the mathematical principles of celestial mechanics, applied to the case of the earth's motion around the sun. It requires, in advance, an exact determination of the ratio of the mass of the sun to that of the earth. This is best found by observations of Venus, which now extend through more than a century and a half, by which the motion of the node of Venus on the ecliptic is determined. This motion is due principally to the attraction of the earth; and from it the proportion between the mass of the earth, and that of the sun is determined. The next step requires a comparison between the distance which a body falls at the surface of the earth from its own gravitation, and the fall of the earth toward the sun as shown by the curvature of its orbit. By combining these various ratios, the distance of the sun is calculated. The fourth method also rests the theory of gravitation. One consequence of the sun's action on the moon is that the latter falls behind about two minutes in its monthly course near the time of the first quarter, and is ahead by the same amount near the last quarter. Knowing the exact amount of this swing, the distance at which the sun must be placed in order to produce it is determined. Each of these four methods has its strong and its weak points; and there is no one of them so much better than all the others that we can rely upon it exclusively. Still, their agreement affords a remarkable proof of the accuracy of astronomical theory, and of the precision with which astronomical measures are made under such difficulties as the observer and computer have to encounter. The astronomer does not use the distance of the sun in his computations, because, as already remarked, this is simply his unit of length. What he actually uses is the sun's parallax; this is equal to the angle which the equatorial radius of the earth subtends when seen at a distance equal to that of the sun. The latest results for this parallax from the four methods are the following.

First method, parallax, 8.802″.
Second method, light, 8.779″.
Third method, mass earth, 8.762″.
Fourth method, moon, 8.773″.

The general conclusion which we reach is that the distance of the sun is very nearly 93,000,000 miles, probably a little more, rather than a little less.

What may seem a yet more wonderful result of celestial measurement is the weighing of the planets and other heavenly bodies. This requires very complex mathematics. But, after all, the principles on which the method rests can readily be made clear. In the case of the planets, there are two methods, one of which can be applied only when a planet has a satellite moving around it. We have already seen that the motion of every planet which, were there no other planet, would take place in an ellipse having the sun in a focus, is changed by the attraction of the other planets. The observation of the deviations, when carefully measured through many revolutions of a planet, enable the mathematical astronomer to compute the ratio of the mass of each attracting planet to that of the sun. This ratio is all that the astronomer requires for his ordinary work.

When the planet has a satellite, its mass can be determined with much more ease and simplicity. The measurement of the distance of the satellite from the planet, carried through a great number of revolutions of the former, enable the astronomer to determine the ratio between the distance of the satellite from the planet, and that of the earth from the sun. Combining this with the time of revolution of the planet, a proportion is shown between the mass of the planet and that of the sun by a law of the same form as the third law of Kepler. The masses determined by astronomical methods are all expressed by taking the mass of the sun as the unit. To translate the result into our ordinary measures of weight, we must know the mass of some one body, say the earth, in pounds or kilograms. How this is done is set forth in the article GRAVITATION.

SIMON NEWCOMB, LL.D.

Astrophysics, or the new astronomy, has revealed in a remarkable manner, through its discoveries during the past quarter of a century, the wonderful ability and resourcefulness of the human mind, making evident that man is almost an infinite being. From this earth of ours, which astronomy teaches is such an insignificant speck among the countless orbs of the universe, we have been able by means of the spectroscope to investigate the physical constitution of the sun, planets, comets and far-off stars; it has become possible to measure motions, not athwart the sky as the older astronomy was able to do, but in the line of sight; and it has been possible to arrange the stars in orderly series, tracing their evolution from the primeval nebula, till now we are well on our way toward the solution of the grandest problem of human investigation, whence came we and whither are we going. Since its birth in 1859, when Kirchhoff discovered the principles of spectrum analysis, astrophysics has advanced by leaps and bounds. This rapid progress was due in a large measure to the improvement of instruments and to the photographic plate. This important acquisition has a two-fold advantage over the human eye: the eye can receive and retain an impression for a small fraction of a second, the photographic plate accumulates impressions, no matter how faint, with the result that by long exposures there is brought to view objects the eye could never hope to see, and secondly, the photograph gives a permanent record that can be examined and studied at leisure. These improved methods of research have made possible a great increase in precision till at the present time, astrophysics is no whit less precise than its older sister, astronomy, the "most exact of all the sciences." A great change has come over our ideas of wave-length. Formerly, the wave-length was looked upon as an invariable property of a line in the spectrum, unalterably fixed by nature, and consequently it was thought that a wave-length determination would give a standard measure of distance more reliable even than that obtained by the use of the International Meter (Michelson, 'Astronomy and Astrophysics,' XIII., 92, 1894). But we now know that the position of the lines in the spectrum may vary with the pressure of the gas in which they are produced, and, moreover, single lines, by the action of a magnetic field, have been separated into as many as nine different components. There seems to be some law regulating the orderly arrangement of the lines in the spectrum in series, and the complete understanding of this law will be one of the important discoveries of the future. The shift of the lines of the spectrum due to motion in the line of sight, which has been shown experimentally in the laboratory, has given rise to many interesting developments in astrophysics, the discovery of an entirely new class of bodies called spectroscopic binaries, the measurement of the axial rotation of the sun and Jupiter, and has confirmed in a magnificent manner the meteoric constitution of Saturn's rings.

Instruments.— The vast increase in accuracy of spectroscopic work was rendered possible by the manufacture of Rowland gratings. Gratings were used as early as 1815 by Fraunhofer and were made by winding fine wire over two exactly similar screws. Rutherfurd of New York ruled some very satisfactory gratings on speculum metal, but these were surpassed in perfection by Rowland's. The invention of the concave grating gave a spectroscope without collimator or objective, thereby eliminating the aberrations brought in by these two lenses. The formula for resolving power which is defined as $r = \frac{\lambda}{d\lambda}$, where $d\lambda$ is the difference of wave-length of two lines of mean wave-length λ which can just be divided, can be easily expressed for gratings, and is the product of the total number of lines of the grating and the order of the spectrum. Ordinary six-inch Rowland gratings have a resolving power of about 400,000. This vast increase in accuracy, coupled with other properties of the grating, namely, normal spectrum, overlapping spectra and astigmatism, whereby comparisons are rendered easy by coincidences, have wonderfully augmented the power of the astrophysicist to determine accurate wave-lengths. The precision of wave-lengths has been still further increased by the use of interferometers. Four different kinds have been invented by Michelson, Perot and Fabry, Hamy, and Lummer. Michelson has been able with his interferometer to compare directly the wave-lengths of the prominent cadmium lines with the International Meter, and has separated lines less than 0.1 tenth-meter apart which appear single with the most powerful gratings, while Perot and Fabry have observed interference with the green mercury line at a difference of path of 790,000 wave-lengths.

Spectra of the Elements.— The invention of the concave grating and the manufacture of nearly perfect gratings, plane and concave, by Rowland enormously increased the accuracy of the wave-lengths in the spectra of the elements. The chief investigations in this field have been carried on by Rowland and his assistants, by Kayser, Runge, Paschen, Hasselberg, Liveing and Dewar, Eder and Valenta, Exner and Haschek, Hartley and Adeney, Trowbridge, Ames, Lockyer, Deslandres, Lohse and others, most of the wave-lengths for which may be found in Watt's 'Index of Spectra.' Accurate measures were made possible by the use of concave gratings and photographic plates. Rowland's 'Table of Solar Spectrum Wave-Lengths' is based on Bell's determination of absolute wave-length ('American Jour. Sci.,' XXXIII., March 1887).

For a discussion of methods of determining wave-lengths, see Perot and Fabry, 'Ann. Chim. et Phys.,' ser. 7, XV., 1899, also XXV., 1902 and Bell, 'Astroph. Jour.,' XV., 157, 1902. The infra-red spectrum of the elements has been investigated by prism and concave grating with the help of bolometer and radiomicrometer by Snow, Lewis, Rubens, Paschen, Julius, Nichols, and others. Short wave-lengths are absorbed by even a few centimeters of air, but Schumann ('Sitz. Akad. d. Wissens. in Wien,' CII., Abth. 2a, 1893), has greatly increased our information of this region of the spectrum. By means of a spectroscopic apparatus in a vacuum with lenses and prisms of fluorite, and photographic plates prepared by himself, a wave-length of λ1.000 was supposed to be reached. More accurate wave-lengths have been determined by Lyman using a concave grating ('Astroph. Jour.,' XIX., 263, 1904), who measured lines in the ultra-violet as far as λ1,033.

Line Series.— That there is some orderly arrangement in the lines of a spectrum was shown by Balmer's law for the hydrogen lines in 1885, and by the presence of numerous triplets in the spectra of magnesium, calcium, and zinc. Further researches by Kayser and Runge, Rydberg, and Schuster with the development by them of empirical mathematical formulæ, have led to a great deal of interesting information regarding these series of lines. The interdependence of astronomy and physics was clearly demonstrated, when Pickering in 1897 discovered a new series of lines in the spectrum of the star ζ Puppis. This was found to be one of the series due to hydrogen produced under conditions not realized in the physical laboratory. However, in a great majority of the elements, the series already discovered comprise only a small percentage of the total number of lines. The exact meaning of these series is as yet unknown, although several very promising attempts have been made to explain them from theoretical considerations. The chief among them may be mentioned those of Julius, Ames, Kövesligethy, and Stoney. Stoney ('Trans. Roy. Soc.' Dublin, 1891) has sought to explain multiple lines from dynamical considerations, comparing the motions of the molecule with those of the bodies of the solar system whose motions in ellipses are perturbed by the presence of other bodies. Stoney, moreover, shows that the conclusions drawn by these dynamical methods may also be considered valid under the electromagnetic theory of light, a statement which receives support from Preston's observations of the Zeeman effect ('Phil. Mag.,' XLVII., 176, 1899). For detailed information on spectral series, see Kayser's 'Handbuch der Spectroscopie,' Vol. II.

Change in Physical Conditions.— The early idea that the position of a line of a spectrum was the result of chance is still further modified by the change of the wave-length of a line resulting from a change in the physical conditions. Jewell noticed while measuring solar spectrum photographs that the arc lines of the comparison spectrum did not in many cases exactly correspond with the lines in the sun. This led to the investigations of Jewell, Humphreys, and Mohler ('Astroph. Jour.,' VI., 169, 1897), on the spectra of an arc under pressure of from one to 15 atmospheres. From measurements of the spectra of 53 elements, it was shown that the lines are shifted by pressure toward the red end of the spectrum, the amount of the shift being directly proportional to the increase of pressure, but being independent of the temperature. For a given element, the shifts of similar lines are proportional to their wave-length, but lines of different series, principal, first and second subordinate, are shifted in the ratios of 1:2:4.

The appearances of lines in a spectrum are greatly altered by other physical conditions. Eder and Valenta have found that argon gives three distinct spectra under different electrical conditions, Schenck that the spark line of Mg at λ4481, which has so often been considered as a sure sign of a high temperature, vanishes if the electrodes become so hot that they glow and begin to melt. Locker has made a great number of investigations on "enhanced" lines, or those which are brighter in the spark than in the arc. He explains their meaning on the assumption that the spark is hotter than the arc, an assumption which is hard to reconcile with other observed phenomena. In this connection, Kayser, in his excellent 'Handbuch der Spectroscopie,' Vol. II., p. 181, says: "We cannot assume any connection between the spectrum and the temperature of the body producing it, and all conclusions which are based on the temperature at which a line or band will appear are quite unsound." Enhanced lines are found in the spectrum of certain stars like α Cygni, and also in the flash spectrum taken at the time of a total solar eclipse of the sun. The presence of these lines is important, but it is difficult at the present time to tell their exact meaning

Solar Spectrum.— The infra-red solar spectrum has been investigated by Becquerel and Lommel to λ9500 by using phosphorescent screens, by Abney to λ27,000, who photographed with a special emulsion of silver bromide and collodion, and by Langley by the use of the bolometer to λ53,386. Rowland's 'Photographic Map of the Normal Solar Spectrum' (Baltimore, 1888), made with a powerful concave grating extending from λ3,000 to λ6,950, and his 'Table of Solar Spectrum Wave-Lengths' (Chicago, 1898), which contain accurate measures of some twenty thousand lines, give the most accurate information we possess of the solar spectrum, and have been accepted by all astrophysicists as the common standard of reference. Rowland's determination of relative wave-lengths leave little to be desired in accuracy. Measures were made by the method of coincidences which is rendered possible by the use of concave grating which permit two overlapping spectra to be photographed on the same plate without change of focus. However, the standard lines of the spectrum have not had their wave-lengths determined with equal accuracy, and they have not been quite properly spaced throughout the spectrum, with the result that at the Saint Louis Conference, 1905, a redetermination of Rowland's standards was regarded as one of the present greatest needs in astrophysics.

Eclipses have furnished interesting developments in the history of spectrum analysis. The spectroscope was first used at the eclipse of 1868 by Janssen in India, when it was shown that the prominences give bright line spectra,

thus showing they are masses of hydrogen gas. The lines were so bright that Janssen looked for them the next day without an eclipse, and found them readily enough. In 1869, the green "coronium" line was discovered; in 1870, Young discovered the "flash spectrum," which was photographed for the first time by Shackleton in 1896. At the eclipses of 1898, 1900, and 1901, Evershed, Lockyer, and Mitchell gave accurate determinations of wave-lengths from these reversed spectra, those of Mitchell being obtained by the use of a grating.

Stellar Spectra.— Modern stellar spectroscopes are best represented by the Mills spectrograph of the Lick Observatory (Campbell, 'Astroph, Jour.,' VIII., 123, 1898), by the Bruce spectrograph of the Yerkes observatory (Frost, 'Astroph. Jour.,' XV., 1, 1902), and that of the Astrophysical Observatory of Potsdam (Hartmann, 'Zeitsch. für Instrum.,' December 1901). The spectrographs are similar in having the slit placed at the focus of the great telescope, and a dispersion of three prisms giving a total deviation of 180°. By means of a guiding eye-piece, it is possible to keep the star's light centrally on the slit during the exposure. Since this exposure may last for four or five hours, it is necessary, in order to have perfect definition, to keep the temperature constant. This is accomplished by means of an automatic temperature control which will keep the prisms of the spectrograph within 0.1° C. during an exposure, when outside in the dome the temperature may change by several degrees. A stellar spectrum is photographed alongside a comparison spectrum in order to determine wave-lengths more accurately, and to give measures of the motion in the line of sight, the most important work of stellar spectroscopy. The spectrograms are most readily reduced by the Hartmann-Cornu formula:

$$\lambda = \lambda_0 + \frac{c}{s - s_0},$$

where λ_0, c, and s_0 are constants and s is the scale reading of the line whose wave-length is desired. The motion in the line of sight in kilometers per second corresponding to the displacement $\Delta\lambda$ is given by

$$V_s = \frac{V_L\,\Delta\lambda}{\lambda}$$

where V_s is the desired velocity of the star, and V_L the velocity of light in kilometers. The most prominent workers in radial velocity have been Campbell, Vogel, Dunér, Frost, Keeler, Hartmann, and Bélopolsky, who have pretty thoroughly surveyed the northern hemisphere. Wright of the Lick Observatory has gone to Santiago, Chile, for similar work in the southern heavens. The observers in this field have entered into co-operation in order to observe the same stars at certain times for the purpose of determining thoroughly the constants of the spectrographs used. Campbell has discovered many stars with variable radial velocities, thus showing they are accompanied by one or more companions. At the present time there are nearly a hundred spectroscopic binaries known with periods which range from a few days to two and a half years.

According to Doppler's principle of motion in the line of sight, the lines will be shifted toward the red end of the spectrum if the distance between the source of light and the observer is increasing, but toward the violet end if this distance is decreasing. The grandest application is seen in Keeler's proof ('Astroph. Jour.,' I., 416, 1895) of the meteoric constitution of Saturn's rings. If meteoric, the linear motion of the rings will be greatest nearest the planet and decrease outward, if solid the rings will rotate as a whole, all particles having the same angular motion, the linear speed increasing from centre to circumference. With solid rings, and a slit placed across the planet's equator, the lines on the side moving toward us would be shifted toward the region of short wave-lengths, the shift being proportional to the linear motion. While for the side moving away from us the lines would be shifted in the opposite direction. Thus, on account of the gradual increase in linear motion from centre to circumference, the lines would be gradually shifted, in the complete spectrum having the effect of lines slightly inclined. Such, however, is not the appearance of the lines photographed by Keeler, and these can be explained only under the assumption that the rings are a collection of small satellites, giving, therefore, a direct confirmation of the mathematical theory of Maxwell.

An important application of line of sight measurements is in determining the motion of the solar system through space. The "apex of the sun's way" may be found from proper motion determinations, or from line of sight measurement used separately, but in a more satisfactory way by applying both methods of research. The right ascension and declination of the point toward which the sun is moving is found from recent measures to be $\alpha = 280°$, $\delta = 35°$ north. This point is situated in the constellation Lyra about 4° from the first-magnitude star Vega. Campbell's determination of the velocity is 19.89 ± 1.52 kilometres per second, a speed which would carry our system over almost exactly four radii of the earth's orbit in a year. When more information is received from the line of sight measurement of the southern hemisphere, a better redetermination of this problem will be possible.

The spectra of stars naturally fall into several types. Secchi's classification is as follows:

Type I.— White or blue stars, the spectrum characterized by the breadth and intensity of the hydrogen lines with metallic lines very faint. This type includes more than half the stars.

Type II.— Yellow stars like our sun, with spectra resembling that of the sun very closely, consisting of a great number of fine dark lines.

Type III.— Red and orange stars, including most of the variables. The spectrum is crossed by numerous dark bands or flutings, which are sharply defined on the blue side and shade off toward the red. α Orionis, Antares, and o Ceti are good examples.

Type IV.— Deep reddish stars, all faint. The spectrum resembles that of Type III., but the flutings are reversed in direction, being sharply defined on the red side. 152 Schjellerup is the best example.

Pickering has suggested a fifth type to include many stars having bright lines in their spectra, and the planetary nebulæ.

Other classifications are due to Vogel, Lockyer, and Miss Maury of the Harvard College Observatory.

One of the grandest problems of scientific research is undoubtedly the question of stellar evolution. By common consent the nebula is regarded as being the primordial matter. The first stage of development is represented, according to Huggins, 'Atlas of Representative Stellar Spectra' (London, 1899), a masterpiece with superb illustrations, by a star like A of θ Orionis, one of the stars of the great nebula. Orion and helium stars are followed in development by the white stars of Secchi's first type. Evolution can be traced step by step, through stages like those represented by the stars α Lyræ, Sirius, Castor (fainter star), α Aquilæ, Procyon, γ Cygni, till we come to the fully developed second type star like Capella and the sun. Increased absorption at the violet end of the spectrum give the red stars of Secchi's third and fourth types, which, according to Huggins, develop in parallel lines. The period of increasing old age is evident from the carbon absorption bands, and it is easy to imagine this absorption increasing in amount till the whole light of the star is cut off. But even at this stage, when the star gives no light, the spectroscope is not powerless to follow, for if the dark star accompanies a bright one, its presence is revealed through a change in the motion of the line of sight. There has been quite considerable discussion as to which star, Sirius or the sun, is in the hotter stage of development. The color of Sirius, and the maximum in its spectrum being more toward the violent end than in the case of the sun, would seem to indicate a higher temperature. Huggins and a great many astronomers think that the sun is in the hottest state, but that the great absorption in its atmosphere compared with that of Sirius, makes the color of the sun yellow The spectrum of the sun is almost identical with that of Capella, which shows that the sun is a star, rendered brighter and bigger on account of its nearness. The stellar magnitude of the sun is —26.4 on the same scale that Sirius is a star of magnitude —1.4. Thus, according to Newcomb, 'Stars,' p. 27, the sun gives us:

10,000,000,000 times the light of Sirius.

91,000,000,000 times the light of a star of magnitude 1.

9,100,000,000,000 times the light of a star of magnitude 6.

The square roots of these numbers show the number of times we should increase the actual distance of the sun in order that it might shine as a star of the corresponding magnitude. Under these conditions, the distance and parallax of the sun would be:

Sirius;	Distance,	100,000:	Parallax,	2″.06
Mag. 1;	Distance,	302,000:	Parallax,	0″.68
Mag. 6;	Distance,	3,020,000:	Parallax,	0″.07

From the large size of the parallaxes, it is evident that the sun must be a very small star in the heavens. But its nearness renders it a very important star, one in which we can study the second stage of stellar development in all its details.

Interesting work has been done by Hale in this field by the application of the spectroheliograph invented by himself. With the 12-inch telescope of the Kenwood Observatory, the prominences and the surface of the sun have been photographed in monochromatic light. More remarkable results have been obtained with the spectroheliograph and Yerkes' telescope ('Astroph. Jour.,' XIX., 41, 1904). Its great focal length of over sixty feet gives a solar image about seven inches in diameter, an increase in size which permits a more detailed study of the sun's surface. A photograph can be taken with the slit of the spectroheliograph at the centre of the K line at λ3933.8, another with the slit moved a trifle to λ3932, and still others with the slit at λ3929 and λ3924. These photographs show bright calcium patches on the face of the sun which Hale has called "flocculi," and the four of them not only differ from photographs taken with the calcium H and hydrogen F lines, but differ materially among themselves. These photographs are explained as being due to a difference in level of the gases, and from these and other results it seems probable that the calcium flocculi are in general made up of a series of columns, which expand as they reach higher levels, and in many cases overhang laterally.

Astrophysical work along entirely different lines has been carried out at the Astrophysical Observatory of the Smithsonian Institution. Langley's bolometer used in connection with a sensitive galvanometer, perfected in the hands of Abbot, can give an automatic record of the energy received from the sun. These bolograms and simultaneous observations made with the actinometer or pyrheliometer, permit an elimination of the variable absorbing effect of the earth's atmosphere, thus giving a measure of the energy from the sun that reaches the outside of the earth's atmosphere, or in other words, the "solar constant." Langley's determination made on the top of Mt. Whitney placed the value of the solar constant at 3.0 calories. Recent observations at Washington ('Astroph. Jour.,' XIX., 305, 1904) show that this number is probably too high, and also that the value is not a constant, but varies altogether about 10 per cent. Another research carried on at the Smithsonian, has been for the purpose of investigating the absorption of the solar envelope, by means of a long focus telescope and bolometer, with the result that it has been shown that likewise this absorption varies in amount. The most interesting part of the whole work has been the comparison with terrestrial temperatures rendered possible by the International Dekadenberichte. With temperature records from 85 localities in the north temperate zone, it has been unmistakably demonstrated that when the solar constant has a very low value terrestrial temperatures are below their average, and at the same time absorption in the solar envelope is large in amount. The interdependence of these variations brings to view one of the most important developments of astrophysics. That terrestrial temperatures should be shown to be closely connected with variations in the sun's heat is very remarkable; it would be still more startling if it should follow that we can forecast great temperature changes — a result which is not impossible.

Literature.—The best books on this subject are Kayser's 'Handbuch der Spectroscopie' and Scheiner's 'Astronomical Spectroscopy' (Frost's translation). S. A. MITCHELL,

Department of Astronomy, Columbia University.

Astruc, as'truk', **Jean,** French physician: b. 19 March 1684; d. Paris, 5 March 1766. He acquired high reputation as an anatomist, and was the author of 'Venereal Diseases' (1736), and other medical works. The work, however, which has immortalized him is purely theological and is entitled 'Conjectures as to the Original Materials of Which Moses Seems to Have Availed Himself in Composing the Book of Genesis' (1753). In this he divides the book of Genesis into two parts, on the ground of the use of Elohim (God) or Yahveh (Jehovah). He holds that these two names for the Deity point to the fact that Genesis was compiled from two parallel, independent documents. His memoir forms the origin of modern criticism on the Pentateuch.

As'trup, Eivind, Norwegian explorer: b. Christiania, 1870; d. 1896. He was a member of the first and second Peary expeditions, 1891 and 1893, and made the first survey of the northern coast of Melville Bay. He perished while on a snowshoe expedition from Dovre, Norway.

Astura, äs-too'ra, a maritime village of Italy, 40 miles from Rome. In its little harbor a high tower is said to stand on the site of the villa of Cicero, where Cicero was slain by order of Antony 43 B.C.

Asturias (as-too'ria), **The,** a former principality of Spain. To this mountainous country of the north of Spain the Goths retreated in the 8th century before the sword of the Saracens. The inhabitants of Asturia are said to be less industrious than the Galicians, and less sociable than the Biscayans. The hereditary prince of Spain has borne since 1388 the title of Prince of Asturia, or of the Asturians, according to the obsolete division into Asturia de Oviedo and Asturia de Santillana, Oviedo and Santillana being the two chief cities of the principality. Since 1838 the principality has been officially known as the province of Oviedo. See Oviedo.

Asty'ages, the last king of Media, reigned 594–559 B.C. In the latter year he was dethroned by Cyrus, who, according to Herodotus, was his grandson. Cyrus revolted in 559, and defeated Astyages, whom he took prisoner, but afterward appointed governor of Hyrcania.

Astyanax, sometimes known as Scamandrius. A Greek legendary character, the son of Hector and Andromache.

Asuncion, å-soon'the-ōn, or **Nuestra Senora de la Asuncion** (in English, *Assumption*), the capital of Paraguay, on the river Paraguay. The principal edifices are the cathedral, several other churches and convents, the president's palace, house of congress, arsenal, custom-house, a college, hospital, railway station, etc. The trade of the town is in Paraguay tea, tobacco, fruits, hides, timber, provisions, manufactured goods, etc. Steamers and sailing vessels ply on the river. The town was founded on the feast of the Assumption in 1537, hence its name. Pop. (1900) 51,700.

Asurnazirpal, ä'soor-nä'zĕr-pal, a king of Assyria from 881 B.C. to 860. He was one of the most warlike of Assyrian kings, and in numerous campaigns enlarged his empire, especially toward the westward, extending it from Lebanon to the Tigris. He also rebuilt Calah, his capital, and left a record of his achievements in the so-called 'Standard Inscription.'

Aswal, ăs'wăl, a Hindu name of the sloth-bear. See Bears.

Asy'lum, a place where persons flee for protection. Under the Mosaic dispensation cities of refuge were set apart to which the slayer might flee so that innocent blood should not be shed, in case the person was not worthy of death — that is, in case the act was accidental and not malicious. But among the ancients, outside of the Jews, it seems that temples, statues to the gods, and altars particularly consecrated for such purposes, constituted places of refuge for persons generally, and it was deemed an act of impiety to remove, forcibly, one who had fled to such an asylum for protection. However, Tiberius abolished all asylums except the temples of Juno and Æsculapius. These asylums finally passed over to the Christian world, and under Constantine the Great, all Christian churches were made asylums for all those who were pursued by officers of justice or the violence of their enemies, and the younger Theodosius, in the year 431, extended these privileges to all courts, gardens, walks, and houses belonging to the Church. In the year 631 the Synod of Toledo extended the limits of asylums 30 paces from every church, and this privilege afterward prevailed in Catholic countries, and it is said to have been a strong armor of defense against the wild spirit of the Middle Ages, and not without good consequences at the time when force often prevailed against justice. But in later times as other and better systems of procedure in the administration of justice became adopted, asylums were abolished in most countries. This seems to have been the origin, nature, and object of asylums, and such the common acceptation of the term, but more recently in some countries, the name has been given to institutions for the protection and care of the poor, blind, deaf and dumb, and lunatics who are incapable of taking care of themselves.

Asy'lum, Right of, in international law, the right which forbids one government to apply its laws to its own or its enemy's subjects when they are within the jurisdiction of another government. Most commonly this right is accorded to a foreign legation to shelter persons subject to the jurisdiction of the State where the legation is situated. It is universally conceded that the right of asylum is not to be applied in the case of ordinary criminals, but it is usually made use of for the protection of political offenders.

Asymmet'ric (as-i-met'rik) **System,** in crystallography, the crystal form now more commonly called "triclinic." It was called asymmetric because it has no plane of symmetry. See Crystal.

Asymptote, ăs'ĭm-tōt (from three Greek words, meaning "not to fall with" or coincide), a term used in geometry to designate a line which continually approaches another line, but never meets it, however far either of them may be prolonged. At least one of the lines must be a curve. Though the very existence of such a line seems paradoxical, it can be demonstrated

on the strictest mathematical principles, as in the case of the hyperbola and its directrix. The term first occurs in the conic sections of Apollonius.

At Odds, the title of a novel by the Baroness Tautphœus (1863), dealing with the vicissitudes of a Bavarian family during a stormy epoch from Hohenlinden to Wagram. It is told with a happy ease and directness; and if it has not the brilliancy of 'The Initials,' is not less clever as a study of character.

Atacama, ä'tä-kä'ma, the name, formerly, of two South American provinces: (1) A northern province of Chile, with an area of 28,380 square miles, and a population (1895) of 59,713. About 1,000 silver and 250 copper mines are worked, and gold is also found in considerable quantities. Salt deposits cover sometimes 50 square miles. Copper, to the value of over $7,500,000 annually, is the chief export to England. Capital, Copiapo. (2) A Bolivian Department, which formerly extended as far north as Peru, and east to Argentina. All that part of the district west of the Andes was ceded, in 1884, to the Chileans, and formed into the Department of Antofagasta, with an area of 60,770 square miles. The recently discovered mines of Caracoles are said to be the most productive silver mines in the world. The former capital, Cobija (pop. 2,380), was long the only port in the district; but the rival port of Antofagasta, founded in 1870, had by 1894 attained a population of 7,946.

A'taca'ma, a desert region on the west coast of South America, formerly belonging partly to Bolivia, partly to Chile, but now belonging wholly to the latter. It lies between the Andes and the sea and much of it at the height of 3,000 to 5,000 feet above the sea. The desert of Atacama proper, a tract almost entirely destitute of water and vegetation, lies partly in the Antofagasta territory of Chile, partly in the province of Atacama. The soil consists of stones and gravel, and the surface is diversified with many mountains. The Salina of Atacama, a salt morass, mostly dried up, has a surface of 1,084 square miles, and lies at the height of over 7,000 feet.

Atacamite, -tak'-, a mineral, originally found as sand in the Atacama province, in northern Chile. It is essentially a hydroxychlorid of copper, having the formula $CuCl_2.3Cu(OH)_2$. It crystallizes in the orthorhombic system, and has a hardness of from 3 to 3.5, and a specific gravity of 3.76. Atacamite is green in color, and commonly occurs either massive or in the form of sand. A coating having the same chemical composition is formed on metallic copper, as the result of prolonged exposure to sea-water or air. Atacamite exists in considerable quantity in various parts of South America, and in Australia; and has been used to some extent as a source of copper. In the United States it is found at Jerome, Arizona.
